While in search of a simple method of determining the efficiency of the respiratory apparatus, Schlomovitz and his co-workers¹ recorded the variations in oxygen usage when measured by the increased oxygen demand occurring after a standardized form of physical activity. The closed circuit apparatus was used. On from three to five separate days, subjects were exercised after a twelve hour postabsorptive resting period. The exercise was carried out for from forty-five to sixty seconds and consisted of the twenty-five-time repetition of the shoulder to floor carriage of a 10 pound dumbbell grasped in each hand, or roughly, 5,000 foot pounds of work. In some instances from five to fifteen seconds elapsed after exercise before the tracings were started. The postexercise determinations were made with the subject breathing into the ordinary basal metabolism recording apparatus containing practically pure oxygen. For this part of the test no corrections were made for temperature, humidity or barometric pressure. Six groups were investigated in this manner: healthy persons and patients having thyroid dysfunction, tachycardia, cardiovascular disease, emphysema and silicosis. Although the number of subjects was not large the results on the whole were quite clear cut, and consistency in reaction on different days was evident. Five emphysematous patients without detectable cardiovascular disturbances gave oxygen consumption figures of a definitely lower range than the healthy subjects. The three patients with organic heart disease showed much higher than normal. The

group with chronic silicosis values in general showed a tendency to drop below the range for healthy persons, which was especially true for those with an uncomplicated second-stage silicosis. Three patients, however, with both second-stage silicosis and organic heart disease had values which reverted to the range of the healthy group, this apparently representing a summation of abnormal values in opposite directions. Schlomovitz and his co-workers believe that consistently abnormally low response to oxygen consumption after exercise in cases of second-stage silicosis is an indication of the presence of a functional or physical disability. Whatever the ultimate verdict on its adequacy as a clinical test, an interesting additional method of study has now become available.

GRADUATE MEDICAL EDUCATION

The higher levels of medical training hold for the moment the center of the stage. Several factors contribute to this focusing of public interest. In the larger cities, at least, medicine is practiced increasingly by those who limit their work to a special field. One of the major divisions of graduate medical education deals with the preparation of the specialist. Examining boards in the specialties have formulated their requirements in terms of advanced study and have stimulated a demand not only for instruction in those phases of medical science related to the specialties but also for supervised clinical experience in the form of apprenticeships of adequate duration and graded responsibility. These apprenticeships are, as a rule, institutional rather than personal and are commonly called residencies. On page 832 is a list of approved residencies containing 3,700 services in twelve specialties in 451 hospitals as a part of the program for the training of specialists. Some institutions offer fellowships which are indistinguishable from residencies but which, in general, tend to lay more stress on systematic instruction and research. For those physicians who are not specialists, continuing instruction is no less important. The ever widening horizon of medical science and the constant development of medical skill in diagnosis and treatment make it imperative for every practitioner to keep abreast of the times by assimilating whatever is of permanent value in the mass of new material presented to the profession. To this end postgraduate schools have been established and postgraduate courses are offered by a number of universities. Such courses have, on the whole, been most profitable to the physicians who attend them, yet there are some who cannot readily leave their practices to avail themselves of these opportunities. To meet the needs of this group extension courses have been organized, usually under the auspices of a state medical society, which bring facilities for instruction almost to the doctor's door. On page 801 is a summary of the survey of this type of teaching which the Council on Medical Education and Hospitals has been conducting during the past year. Evidence collected from half of the states abundantly demonstrates the value of these efforts to enable the somewhat isolated practitioner to enjoy frequent association with the leaders of the profession.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

New Maternity Center.—The establishment of a maternity center in Jonesboro is under way, newspapers reported June 3. It is planned to offer complete maternity service through regularly conducted clinics for antepartum care with hospitalization for delivery. Only indigent and low income groups will be eligible for the service. The center will be conducted by the medical staff of St. Bernard's Hospital with the assistance of the American Legion auxiliary and the state board of health. In quoting figures showing the need for a unit in the county, it was stated that infant mortality in the state was 52.2 per thousand live births in 1937, while rural Craighead County showed a rate of 72.2 and Jonesboro a rate of 114.3 for the same period.

CALIFORNIA

Personal.—Dr. Charles Weiss, director of the research laboratories of Mount Zion Hospital, San Francisco, has received a grant from the committee on medical research of the National Tuberculosis Association to be used for a study of the nature of the lysis of tubercle bacilli in cellular exudates. Dr. Weiss will be assisted by Alex Kaplan, formerly research fellow in physiology, University of California.—Dr. Ambrose P. Merrill Jr. has been appointed assistant superintendent of the San Francisco County Hospital, San Francisco.—Dr. Fred H. Lawrence has been appointed medical director of the Southern Pacific Hospital, San Francisco.—Dr. Archibald W. Truman, Bellflower, head of the medical department of the world's general conference of Seven Day Adventists, has been appointed superintendent of the denomination's sanatorium in Shanghai, China.

COLORADO

University News.—Under the will of the late Dr. William C. Johnson, professor of pathology, University of Colorado School of Medicine, Denver, this school, on the death of relatives, will receive the remainder of a \$35,000 trust fund for study and research of the pathology and diseases of infancy and childhood. The will also bequeathed Dr. Johnson's medical books to the school library.

State Medical Meeting in Estes Park.—The Colorado State Medical Society will hold its sixty-eighth annual session at the Stanley Hotel, Estes Park, September 8-10, under the presidency of Dr. William T. H. Baker, Pueblo. Out of state speakers will include:

- Dr. Irvin Abell, Louisville, Ky., President, American Medical Association, The Acute Abdomen: Differential Diagnosis.
- Dr. James W. Kennedy, Philadelphia, Vaginal Hysterectomy and Its Indications.
- Dr. Claude D. Head Jr., Washington, D. C., Serum Therapy in Pneumococcal Pneumonia and Recent Reduction in Pneumonia Mortality Rates.
- Dr. Gilbert J. Thomas, Minneapolis, Diagnosis and Treatment of Subacute and Chronic Lesions of Tuberculosis in the Genital Tract.

Included among the Colorado physicians on the program are:

- Drs. Edward R. Murrage and George W. Stiles, Jr., Denver, Common Animal Parasites Transmissible to Man.
- Dr. Charles Walter Metz, Denver, Choice of Anesthetic Agent.
- Walter M. Scott, Ph.C., Denver, How to Secure a Safe Milk Supply.
- Dr. Vernon G. Jeurink, Denver, The Office Treatment of Common Rectal Disorders.
- Dr. Clarke H. Barnacle, Denver, Newer Methods of Treatment in Psychiatry.
- Dr. Luman E. Daniels, Denver, Brain Tumors with Focal Symptoms.
- Dr. Lyman W. Mason, Denver, Role of the Thyroid in Menstrual Disorders and Sterility.
- Dr. John H. Spillane Jr., Colorado Springs, X-Ray Pelvimetry.
- Dr. John B. Farley, Pueblo, Treatment of Placenta Praevia.
- Harold Clark Thompson, L.L.R., Denver, What Is Expected of the Physician and Surgeon in Compensation Cases?
- Dr. William Senger, Pueblo, The Problem of Difficult Inguinal Hernias.
- Drs. George B. Kent and Kenneth C. Sawyer, Denver, Exophthalmic Goiter: Management of the Poor Surgical Risk.
- Dr. Edgar Durbin, Denver, Heart Disease in Colorado.
- Wilton W. Cogswell, D.D.S., Colorado Springs, Oral Lesions as Sources of Infections: Their Diagnosis and Treatment.
- Dr. Kemp G. Cooper, Denver, Causes of Dizziness.

- Dr. William C. Service, Colorado Springs, The Role of Allergy in Migraine.
- Dr. Franklin P. Gengenbach, Denver, Present Status of Contagious Diseases of Childhood: Prevention and Treatment.
- Drs. Carl S. Gydesen and Bradford J. Murphey, Colorado Springs, Some Endocrine Dyscrasias Associated with Conduct Disorders in Colorado Springs Children.

There will be a symposium on automobile fractures and round table discussions. At the annual banquet Dr. John W. Amessee, Denver, will give an address entitled "Behind the Scenes in European Medicine."

ILLINOIS

Dr. Shaughnessy Again Director of Laboratories.—Howard J. Shaughnessy, Ph.D., for the past year associate professor of bacteriology and public health at the University of Colorado School of Medicine, Denver, is again director of laboratories of the state department of health. Dr. Shaughnessy held the position from 1930 to 1937, when he went to Denver.

Chicago

Society News.—The Chicago Council of Medical Women was addressed June 8 by Drs. Irene C. Sherman on "Psychosis in Children" and Beulah C. Bosselman, the treatment of psychoses; Dr. Melvin F. O. Blaurock showed a motion picture on metrazol treatment.

New Neuropsychiatric Unit.—Construction is expected to start late this year on a neuropsychiatric institute on the grounds of the Research and Educational Hospital, according to the state department of public welfare. The building will cost \$1,250,000, of which \$544,909 was supplied by a PWA grant. Present plans call for two towers of eight floors each to be connected by a two story unit. Fifty beds will be available for neurologic patients, while 100 will accommodate psychiatric patients. Arrangements have been made whereby the four medical schools in the city, Illinois, Northwestern, Chicago and Loyola, will have access to the psychiatric beds for teaching purposes. Twenty beds have been allotted to Dr. Paul L. Schroeder, director, Institute for Juvenile Research, for study and research. The neuropsychiatric institute will be administered by Dr. Major H. Worthington, director of Research and Educational Hospital; Drs. Harold Douglas Singer, professor of psychiatry, and Eric Oldberg, professor of neurology and neurological surgery, University of Illinois College of Medicine, will direct the psychiatric and neurologic divisions, respectively.

IOWA

Personal.—Drs. George B. Maxwell, Davenport, and George A. Wiggins, Milan, were recently presented with gold buttons by the Iowa and Illinois Central District Medical Association in recognition of their completion of fifty years in the practice of medicine.

Society News.—A special meeting of the Linn County Medical Society was addressed in Cedar Rapids August 9 by Drs. William D. Haggard, Nashville, Tenn., on "Clinical Syndromes of Gallbladder Disease, Their Differentiation and Treatment," and Gershom J. Thompson, Rochester, Minn., "Transurethral Resection of the Prostate." Dr. James S. McLester, Birmingham, will discuss "Clinical Aspect of Nutritional Deficiency" before the society September 15.—At a meeting of the Dallas-Guthrie County Medical Society in Woodward July 21 the speakers included Drs. Lawrence D. Smith, Des Moines, on "Fundamentals of Endocrinology" and Ralph A. Reis, Chicago, "Treatment of Fibroids in Pregnancy."—Dr. James J. Morrow, Austin, Minn., discussed military medicine before the Fayette County Medical Society July 21.

—The Hardin County Medical Society was addressed in Eldora July 29 by Dr. Milo G. Meyer, Marshalltown, on psychoneurosis.—Dr. Arthur E. Davis, Seymour, addressed the Wayne County Medical Society July 14 on rheumatism.

LOUISIANA

New Director of Child Welfare.—Dr. Christopher L. Mengis, Winnsboro, formerly director of the Franklin Parish health unit, has been appointed director of the division for services to crippled children in Louisiana. While the division was created by the 1936 legislature, no funds were available until 1938, when an appropriation was made. Now in process of organization, the division will be managed by the bureau of parish health administration of the state board of health. Dr. Mengis graduated at Tulane University of Louisiana School of Medicine, New Orleans, in 1900. Recently he has been conducting clinics for crippled children throughout the state.

Women in Medicine.—An exhibit of memorabilia showing the history of women in medicine is now on display at the Rudolph Matas Library, Tulane University of Louisiana School of Medicine, New Orleans. Some were lent to the library by the Orleans Parish Medical Society and others represent the personal collection of Dr. Mary Elizabeth Bass, assistant professor of clinical medicine at Tulane, a former president of the American Medical Women's Association. Illustrations include a copy of the most ancient known pictorial record of a woman physician, dated 3000 B. C.; it shows a woman physician presenting a boy to Isis; the patient has poliomyelitis. Others show a woman teaching anatomy to a fourteenth century class, a picture of Ann Morandi Manzolini dissecting a brain in 1760, a sketch of Lady Mary Montagu, pioneer sponsor of vaccination for smallpox, and a picture of St. Elizabeth and her thirteenth century dispensary. Among other material of historical interest is a photograph of Dr. Elizabeth Cohen, the first woman physician in New Orleans, who died in 1921.

MARYLAND

Committee on Industrial Health.—At a meeting of the council of the Medical and Chirurgial Faculty of Maryland in Baltimore June 27 the following committee on industrial health was appointed: Drs. Allen D. Lazenby, chairman, Nathan B. Herman, William H. Howell, Raymond H. Hussey, Frank S. Lynn, Esther L. Richards, Robert H. Riley, Harry M. Robinson and Huntington Williams, all of Baltimore; Victor F. Cullen, State Sanatorium; William D. Noble, Easton; Edward P. Thomas, Frederick, and Richard B. Norment Jr., Hagerstown.

Conference of Social Welfare.—The Maryland State Conference of Social Welfare held its annual meeting in Baltimore June 9-11. The program was devoted to section meetings on tuberculosis, vocational education and rehabilitation, trends in recreational programs, community adjustment of the mentally deficient, community problems in the care of children discharged from institutions, rural and urban housing problems, and problems of special significance in the care of dependent children and the administration of relief. The speakers in the symposium on tuberculosis included:

Dr. Thomas B. Aycock, University Hospital.
Dr. Humphrey Warren Buckler, city health department of Baltimore.
Mr. W. B. Matthews, state tuberculosis association.
Dr. Huntington Williams, commissioner of health of Baltimore.
Dr. William A. Bridges, superintendent, Eudowood Sanatorium.
Miss Pauline Bushey, board of state aid and charities.
Dr. William Ross Cameron, deputy state health officer, Hagerstown.
Dr. Charles H. Halliday, epidemiologist, state department of health.
Mrs. Jean Loosli, nutritionist, state department of health.

MICHIGAN

Personal.—Dr. Charles E. Long has resigned as a member of the board of education of Grand Haven after sixteen years' service.—Dr. Cornelius D. Mulder recently retired as a member of the Spring Lake board for education, having served for twenty-two years.—Dr. Vladimir K. Volk, Saginaw, was recently appointed to fill the newly created position of medical superintendent of Saginaw County hospitals; he is also health officer of the county.

Hospital Building Program.—The W. K. Kellogg Foundation of Battle Creek, the WPA and the PWA are cooperating with the communities of Allegan, Coldwater and Hillsdale in hospital building projects. Federal approval has already been given to a unit in Coldwater and work was expected to begin within a few days, it was reported July 31. Fifty beds are planned for the hospital. The units in Allegan and Hillsdale will have twenty-eight and sixty beds respectively, if they are approved by the government. The total cost of the units will be \$600,000, one half of which will be contributed by the Kellogg Foundation.

MINNESOTA

CCC "Surgeon" Court-Martialed and Dismissed.—Hugh David Halstead, following his plea of guilty in the District Court at Minneapolis, June 1, to a charge of practicing medicine without a license, was sentenced to one year in the Minneapolis workhouse and placed on probation, according to the state board of medical examiners. The defendant had been tried before a military court at Fort Snelling April 19 on a charge of misrepresenting his rank as an officer and misrepresenting his qualifications as a physician. He pleaded guilty to both charges and was dismissed from the military service of the United States. In 1934 Halstead, after working as a truck driver and shoe salesman, worked as an intern at the Minneapolis General Hospital. From Jan. 1, 1935, to June 25 he was an intern at the Deaconess Hos-

pital, Minneapolis, at a salary of \$50 a month. When subsequent inquiry was made at the Deaconess Hospital as to why no investigation had been made of Halstead's credentials as a physician, officials at the hospital stated that because he had been at the Minneapolis General Hospital it was assumed that his credentials were in order. July 5, 1935, after fraudulently representing himself as a physician and a graduate of the Northwestern University Medical School and that he was licensed to practice medicine in Illinois, Halstead signed a contract to act as surgeon for the CCC camps in Minnesota. No investigation was made at that time to ascertain his qualifications. He was assigned to various camps, receiving a commission in September 1935 as a first lieutenant in the medical reserve corps of the U. S. Army; this commission was obtained on his fraudulent representations with respect to his medical training. Following his marriage in 1936 Halstead was paid \$262 a month by the government. In February 1938 inquiry was made concerning his qualifications, which led to his court-martial April 19. The only medical education he ever received was in the extension division of the University of Minnesota 1930-1931, when he was enrolled in a class in general inorganic chemistry. In the year 1931-1932 he failed in a similar course at the university.

MISSISSIPPI

Changes in Health Officers.—Dr. Benjamin F. Hand Jr., formerly of Waynesboro, has been appointed itinerant health officer for the state board of health to aid county health officers in the examination of preschool children, it is reported. Dr. Benjamin A. Stafford Jr., formerly of Temple, Texas, has been appointed health officer for the Sharkey-Issaquena county unit, succeeding Dr. Robert H. De Jarnette, who was transferred to Alcorn County. Sharkey and Issaquena counties made joint appropriations for a combined full time health unit with centers in each county.

MISSOURI

Society News.—The Northeast Missouri Medical Society was organized at a meeting of physicians of Clark, Scotland and Lewis counties in Kahoka recently. Dr. James R. Bridges was elected president and Dr. Harold G. Pudliner, Canton, secretary.

Hospital Association Adopts District Plan.—To correlate its activities, the Missouri Hospital Association has divided the counties of the state into four districts, with a chairman in charge of each. It is planned to draw the various hospital workers of the state into these four units, each to serve as a center for the hospitals in the district. The units will be known as the Northeast, Southeast, Southwest and Northwest districts. The Missouri Hospital Association began in August to publish a monthly bulletin.

MONTANA

Scientific Session of State Society.—The Medical Association of Montana will hold its annual scientific session in Lewistown September 5-6 with the Fergus County Medical Association acting as host. The following will speak:

Dr. Archibald F. O'Donoghue, Sioux City, Fractures of the Spine and Pelvis Associated with Other Injuries Following Automobile Accidents.
Dr. John R. Kleyla, Omaha, Pneumonia.
Dr. Raymond W. McNeely, Chicago, Are Herniorrhaphies as Successful as They Should Be?
Dr. Ashley W. Morse, Butte, The Sinus Problem.
Dr. Lawrence G. Dunlap, Anaconda, Accuracy in Eye Examinations.
Dr. Robert G. Allison, Minneapolis, X-Ray Therapy as Related to Treatment of Sinus Disease, Erysipelas and Skin Conditions.
Dr. Henry Close Hesselstine, Chicago, Endocrinology in Gynecology.

Dr. Irvin Abell, Louisville, Ky., President, American Medical Association, will deliver the principal address at the annual banquet September 5 on "The Changing Social Order of Medicine." Dr. James C. MacGregor, Great Falls, president, state medical association, will also speak, and Dr. Thomas J. B. Shanley, Butte, will be the toastmaster. The Montana Academy of Oto-Ophthalmology will meet in Lewistown September 4.

NEBRASKA

Personal.—The Scotts Bluff County Medical Society honored Dr. Frank W. Plehn, Scottsbluff, at its June meeting in recognition of his completion of forty-five years of practice; he has practiced thirty-one years in Scottsbluff.—Dr. and Mrs. Charles W. Doty, Beaver Crossing, were recently honored with a community reception in recognition of Dr. Doty's fiftieth anniversary in practice.—George Robert Coatsy, Ph.D., professor of biology, State Teachers College, Peru, has been appointed protozoologist of the U. S. Public Health Service.

NEW HAMPSHIRE

Society News.—Dr. Lawrence R. Hazzard, Portsmouth, was elected president of the New Hampshire Surgical Club at the annual meeting recently in Nashua. Drs. Charles F. Nutter, Nashua, and William J. Paul Dye, Wolfeboro, were elected vice president and secretary, respectively. At a joint session with the Hillsborough County Medical Society Dr. Harold G. Lee, Boston, spoke on "Low Back Pains."

NEW YORK

Outbreaks of Typhoid.—Five cases of typhoid occurred between June 23 and July 8 among a group of workmen building roads in Columbia County. The outbreak was attributed to drinking water, which was obtained from two springs known to have been polluted, though the exact source of the infection had not been determined, according to *Health News*.—Thirteen cases of typhoid appeared among residents and visitors in the village of Esperance during July. The only food or drink common to all the patients was raw milk. Investigation showed that on June 15 the dairy that supplied the families affected had begun to obtain extra milk from a new producer, who was found to be a carrier. He had previously sold his milk only to an ice cream plant, where there was adequate pasteurization.

Federal Worker Denied Choice of Physician.—Five WPA workers in Buffalo, injured June 27 while working on the new Buffalo Civic Stadium, were taken to the Marine Hospital, although other hospitals were nearer, because they were federal workers, according to the *Bulletin* of the Medical Society of the County of Erie. The president of the county medical society took exception to this action because it denied free choice of physician or hospital, as provided in the workmen's compensation law of New York. On inquiry the families of the injured workers agreed that they preferred to have the services of their family physicians. One family physician, however, visited his patient at the Marine Hospital and was not allowed to treat him as a compensation case. The industrial commission of the state, when asked for a ruling in this case, stated that "when employees are in WPA service, the state of New York has no jurisdiction and the Compensation law does not cover, as they are employed by and paid 100 per cent by the Federal Government."

New York City

Personal.—Dr. Carl Eggers was elected president of the Alumni Association of the College of Physicians and Surgeons of Columbia University at its recent annual meeting. Dr. Louis M. Rousselot is secretary.

Burn Six Tons of Marihuana.—More than six tons of marihuana, valued at \$13,000, was burned by narcotic control officials July 29 in Brooklyn. The collection was gathered from fields in the five boroughs by the Narcotic Bureau of the Municipal Police Department.

A New Foundation.—The William J. Wollman Foundation was recently organized by the executors of Mr. Wollman's estate to administer a trust fund of \$5,000,000, which will become available on the death of Mr. Wollman's sister, to be devoted to public charitable, educational and scientific purposes. Mr. Wollman, formerly head of the securities firm of William J. Wollman and Company, died March 27, 1937.

Course on Eye Conditions.—New York University and Columbia University are again offering courses on eye conditions in cooperation with the bureau of services for the blind, New York State Department of Social Welfare, it is announced. The course is given in evening sessions at both universities and is attended by teachers, social workers, school and public health nurses and workers in allied fields. Inquiries may be addressed to the Secretary, Teachers College, Columbia University, 525 West One Hundred and Twentieth Street; Prof. Helen C. Manzer, School of Education, New York University, Washington Square, or Miss Ruth B. McCoy, director, prevention of blindness service, New York State Department of Social Welfare, 205 East Forty-Second Street.

Cornell to Exchange Students with Havana.—Committees representing Cornell University Medical College and the University of Havana Faculty of Medicine have arranged for exchange of students and teaching staff for periods of study. Four undergraduate students and/or members of the teaching staff of Cornell will study parasitology, tropical diseases or any other subject of special interest for six weeks in the summer in Havana under the auspices of the university. Three

undergraduates in medicine and/or members of the teaching staff of the University of Havana will have the opportunity of studying at Cornell for a period of eight weeks, one each in the fall, winter and spring. Each university agreed to grant to each visitor on satisfactory completion of the work a certificate covering the studies pursued and the time employed thereon. The studies at the respective schools will be supervised by special committees. Dr. Wilson G. Smillie is chairman of the committee at Cornell and Dr. Alberto Inclán of the one in Havana. The agreement is in effect for one year.

NORTH CAROLINA

News of Health Officers.—Dr. Gaston W. Rogers, U. S. Army Medical Corps, retired, has been appointed assistant district health officer on a full time basis in charge of Chatham, Person and Orange counties with headquarters in Pittsboro, it is reported.—Dr. Fletcher R. Adams, formerly of Davidson, has been appointed head of the health unit in Union County.—Dr. Murray P. Whichard, Edenton, has been appointed health officer of Craven County, succeeding Dr. John S. Anderson, New Bern, who recently went to Cabarrus County.

Open Campaign Against Syphilis.—The North Carolina state board of health opened its campaign against syphilis July 1, when funds became available from the Reynolds Foundation, created several months ago by the North Carolina tobacco family, and from the U. S. Public Health Service under the LaFollette-Bulwinkle law. About \$120,000 furnished by the Reynolds Foundation will be spent in twenty counties enlarging and increasing the number of clinics. Forty-eight clinics are now operating in these counties and it is expected that thirty-five physicians and as many nurses will shortly be added to their staffs. Cities and counties in this group will match the funds supplied by the Reynolds Foundation. For the area outside these twenty counties the board of health has a state appropriation of \$25,000 a year and a federal grant of \$85,000, and much of this money will be matched by city and county appropriations.

OHIO

Personal.—Dr. Joseph T. Smith, assistant clinical professor of obstetrics, Western Reserve University School of Medicine, Cleveland, has joined the faculty of Tufts College Medical School, Boston, to conduct short courses in gynecology and obstetrics for general practitioners under the graduate education plan of the Bingham Associates Fund.

Honored for Fifty Years of Practice.—Dr. John G. Wishard, Wooster, was the guest of honor at the annual banquet of the Wayne County Medical Society in Orrville recently, celebrating his completion of fifty years in the practice of medicine. Dr. Wishard, who graduated from the Medical College of Indiana, Indianapolis, in 1888, founded the American Hospital in Teheran, Persia, and was its director for twenty years.—Dr. Frederick S. Heller, Oak Harbor, received a gold plaque from the Ottawa County Medical Society at a meeting in Danbury July 21, in honor of his fifty years of medical practice. Dr. Heller graduated from the University of Michigan Medical School, Ann Arbor, in 1888.

PENNSYLVANIA

District Meeting.—The annual meeting of the Sixth Council District of the Medical Society of the State of Pennsylvania was held at the Birmingham School, Birmingham, August 25. The speakers included Drs. Charles W. Dunn and Gilson C. Engel, Philadelphia, on "Review of Newer Aspects of Endocrine Therapy" and "Diseases of the Thyroid, Their Diagnosis and Treatment" respectively. Dr. Peter H. Dale, State College, gave a history of the Center County Medical Society and several officers of the state society discussed current social and economic questions.

Philadelphia

Society News.—The Philadelphia College of Physicians will receive all pamphlets and data on tuberculosis accumulated by the late Dr. Lawrence F. Flick, according to a specific bequest in his will, newspapers report.

Personal.—Dr. Hayward R. Hamrick has been appointed medical director of the Curtis Clinic of Jefferson Medical College.—Dr. Chevalier Jackson has been reelected president and professor of bronchoscopy at the Woman's Medical College of Pennsylvania. Although Dr. Jackson has retired from clinical work, he will continue with didactic teaching. Temple University School of Medicine announces that Dr. Jackson has

resigned as professor of bronchoscopy and esophagology and has been elected honorary professor of broncho-esophagoscopy. He has also been designated consultant in research in the broncho-esophagologic laboratories at Temple.

SOUTH CAROLINA

Piedmont Assembly.—The fourth annual Piedmont Post Graduate Clinical Assembly will be held at the Anderson County Hospital, Anderson, September 13-15. Among the speakers will be Drs. Samuel F. Ravenel, Greensboro, N. C., on "Nephritis in Children"; Kenneth M. Lynch, Charleston, "Lung Changes in Pneumonia," and William H. Kelley, Charleston, "Management of Lobar Pneumonia." On the last day there will be a joint meeting with the South Carolina division of the Southeastern Surgical Congress, with Drs. Frank H. Lahey, Boston, and Robert Lee Sanders, Memphis, Tenn., on "Diseases of the Thyroid Gland" and "Common Diseases of the Colon" respectively. The Anderson County Medical Society will sponsor a dinner in the evening at which Dr. Lahey will speak on anesthesia and Dr. Sanders on disease of the gallbladder.

TENNESSEE

Dr. Shoulders Honored.—The Nashville Academy of Medicine gave a dinner July 26 in honor of Dr. Harrison H. Shoulders, Nashville, secretary of the Tennessee State Medical Association and editor of the association's journal, who was elected Speaker of the House of Delegates of the American Medical Association at the San Francisco Session. Dr. Irvin Abell, Louisville, Ky., President of the American Medical Association, made the principal address. Other speakers who paid tribute to Dr. Shoulders included Drs. Elmer L. Henderson, Louisville; William D. Haggard, William B. Anderson, Alfred Blalock and Charles C. Trabue IV, Nashville; Ernest R. Zemp, Tom R. Barry and Elbert G. Wood, Knoxville; Hiram B. Everett, Memphis, and George Williamson, Columbia; Charles Cornelius, attorney, and Judge W. H. Swiggert. Dr. Holland M. Tigert, Nashville, was toastmaster. Dr. William C. Dixon, speaking for the Nashville profession, presented to Dr. Shoulders a gavel "cut from a hickory tree from the home of Andrew Jackson and to be used in presiding over the House of Delegates."

TEXAS

Changes in Health Officers.—Dr. Robert W. Taylor, Lufkin, has been appointed health officer of Lufkin, succeeding Dr. Denman C. Hucherson, resigned.—Dr. Don Price, secretary of the Henderson County Medical Society, has been named health officer of Athens to succeed Dr. John K. Webster.—Dr. Isaac F. Hudson is the new health officer of Stamford, succeeding the late Dr. Nathan H. Bickley.

Hospital News.—The Raymondville Hospital was opened for public inspection June 5. The hospital is owned and operated by Drs. Charles C. Conley and Ervin E. Baden on an open staff basis, any physician in good standing in the Cameron-Willacy Counties Medical Society being permitted to use it.—A new hospital will be constructed in Littlefield costing \$50,000 and accommodating twenty-five patients, it is reported.—The new Montgomery County Hospital, Conroe, will soon be ready for patients, it is reported. The building cost \$106,000 and will provide for forty patients.

UTAH

Plague Infection.—According to *Public Health Reports*, plague infection was found in tissue from one ground squirrel secured June 28 at the south end of Strawberry Reservoir, Wasatch County, and a pool of 132 fleas collected from fifty-two ground squirrels shot July 2 on Dean Ranch, 1 mile west of Woodruff, Rich County.

WEST VIRGINIA

State Medical Election.—Dr. Ray M. Bobbitt, Huntington, was elected president of the West Virginia State Medical Association at its annual session in White Sulphur Springs July 12, succeeding Dr. Charles W. Waddell, Fairmont. Drs. Harold D. Gunning, Roncverte, and James L. Blanton, Fairmont, were chosen vice presidents. White Sulphur Springs was again chosen as the place for the next annual meeting.

Society News.—Dr. George E. Gwinn, Seckley, addressed the Fayette County Medical Society, Oak Hill, June 7, on "Collapse Therapy in Pulmonary Tuberculosis."—Dr. Arthur

M. Shipley, Baltimore, addressed the Kanawha Medical Society, Charleston, June 14, on "Surgery of the Heart."—At the meeting of the Monongalia County Medical Society, Morgantown, recently, Dr. John C. Kerr, Wheeling, discussed "Common Skin Diseases of Interest to the General Practitioner." Dr. Charles C. Higgins, Cleveland, addressed a joint meeting of Monongalia, Marion and Harrison county medical societies at Morgantown recently on "Prevention of Recurrent Calculus Formation."

WISCONSIN

District Meetings.—The annual meeting of the Fourth Councilor District of the State Medical Society of Wisconsin was held in Lancaster recently. The guest speakers were Drs. Gordon B. New, Rochester, Minn., on "The Diagnosis and Treatment of Mouth Lesions from the Standpoint of the General Practitioner"; John B. MacLaren, Appleton, "Skull Fractures"; James C. Sargent, Milwaukee, "Fundamental Principles in Conservative Renal Surgery," and Edwin F. Schneiders, Madison, "Obstetrical and Gynecological Emergencies." Dr. Sargent, president of the state medical society, also discussed the society's program at the evening banquet.

Meetings of Specialists.—The Central Wisconsin Society of Ophthalmology and Otolaryngology held its recent annual meeting in Marshfield. The speakers were Drs. Avery D. Prangen, Rochester, Minn., on "Anomalies of the Convergence-Divergence Mechanism"; Louis E. Prickman, Rochester, "Allergy in Relation to Eye, Ear, Nose and Throat"; Arthur Kovacs, Milwaukee, "Treatment of Nasal Fractures and Plastic Surgery of the Nose," and Stephan Epstein, Marshfield, "Roentgen Therapy in Eye, Ear, Nose and Throat."—The section on radiology of the State Medical Society of Wisconsin held its annual meeting June 3-4 in Eau Claire. Dr. Edward Schons, St. Paul, was the guest speaker, discussing super-voltage therapy. Round table discussions formed the remainder of the program.

State Medical Meeting at Milwaukee.—The ninety-seventh annual meeting of the State Medical Society of Wisconsin will be held in Milwaukee September 14-16 under the presidency of Dr. Albert E. Rector, Appleton. Guest speakers who will address general sessions include:

- Dr. Borden S. Veeder, St. Louis, Relation of the Private Physician to the School Health Program.
- Dr. Wright R. Adams, Chicago, Electrocardiography in the Prognosis and Treatment of Diseases of the Heart by the General Practitioner.
- Dr. Samuel Brown, Cincinnati, Differential Diagnosis of Abdominal Lesions by Roentgenography.
- Dr. David Slight, Chicago, Emotional Problems and Disorders in General Medical Practice (the Rogers Memorial Lecture).
- Dr. Charles P. Emerson, Indianapolis, The Power of Suggestion.
- Dr. Carey P. McCord, Detroit, Occupational Diseases in Medical Practice.
- Dr. William L. Benedict, Rochester, Minn., Office Treatment of Eye Injuries.
- Dr. Howard H. Cummings, Ann Arbor, Mich., Office Treatment of Gynecologic Conditions.
- Dr. Herman L. Kretschmer, Chicago, The Significance of Blood in the Urine.
- Dr. John S. Coulter, Chicago, Indications and Contraindications for Use of Physical Therapy in General Practice.
- Dr. Morris Edward Davis, Chicago, Accidents in Labor.
- Dr. Max M. Peet, Ann Arbor, Mich., Sympathectomy and Hypertension.
- Dr. James H. Hutton, Chicago, Endocrine Preparations of Proved Therapeutic Value.

Dr. John H. J. Upham, Columbus, Ohio, will contribute a commentary on the general program Thursday afternoon. In addition, the following guests will address section meetings:

- Dr. Samuel Saling, Chicago, Septum Deviation in Relation to the Twisted Nose.
- Dr. John J. Shea, Memphis, Tenn., Laryngologic Aspects of Hematopoietic Disease.
- Dr. Charles B. Puestow, Chicago, Surgery of the Common Bile Duct; The Effect of Drugs on Intestinal Motility.
- Dr. Arthur F. Bratrud, Minneapolis, The Injection Method for the Treatment of Hernia.
- Dr. Raymond W. McNealy, Chicago, Preparation of the Jaundiced Patient for Operation.
- Dr. Harry E. Mock, Chicago, Conservative Treatment of Gallbladder Disease.
- Dr. Kretschmer, Management of Prostatic Disease.
- Dr. Meyer Wiener, St. Louis, Plastic Surgery of the Lids and Sockets.
- Dr. Benedict, Low Grade Occult Inflammatory and Neoplastic Diseases of the Orbit.
- Dr. Roger L. J. Kennedy, Rochester, Minn., Intestinal Upsets in Children.

Special features of the meeting will be a symposium on "Common Office Treatments," a "Question Box" Friday afternoon with Dr. Eben J. Carey, Milwaukee, as master of ceremonies, and round table luncheons Thursday and Friday noons at the Hotel Schroeder.

GENERAL

Examination in Urology.—The next examination of the American Board of Urology will be held in New York Jan. 13-15, 1939. All applications should be received not later than October 1. Additional information may be obtained from Dr. Gilbert J. Thomas, secretary, 1009 Nicollet Avenue, Minneapolis, Minn.

Society News.—Dr. Warren T. Vaughan, Richmond, was chosen president-elect of the American Society for the Study of Allergy at its recent annual meeting and Dr. Harry L. Alexander, St. Louis, was installed as president. Dr. Robert L. Benson, Portland, Ore., was elected vice president and Dr. James Harvey Black, Dallas, Texas, secretary. The 1939 meeting will be held in St. Louis, in conjunction with the annual session of the American Medical Association.—The American Association for the Study of Neoplastic Diseases will meet in Washington, D. C., September 8-10.

Coroners to Meet in St. Louis.—The National Association of Coroners will hold its annual convention in St. Louis August 29-31 at the Statler Hotel. Among the speakers will be:

Dr. Samuel H. Gray, St. Louis, Causes of Sudden Death.
Dr. Samuel R. Gerber, Cleveland, Studies of Alcoholism and Its Relation to Traffic Accidents.
Dr. Matthew W. Weiss, St. Louis, Signs of Criminal Abortion.
Dr. Downey L. Harris, St. Louis, Pathology and Communicability of Human Rabies.
Dr. Thomas B. W. Leland, San Francisco, Experience as Coroner in Safety Matters.
Gordon H. Scott, Ph.D., St. Louis, Use of the Spectrograph.

Tuberculosis Hospital and Sanatorium Directory.—The National Tuberculosis Association has compiled by states the sanatoriums, preventoriums and general hospitals having departments for tuberculous patients in the United States, Alaska, Hawaii, Puerto Rico and the Philippine Islands. The institutions are listed alphabetically under the several states except that the state sanatoriums are listed first in all cases and the federal government hospitals are listed separately. There is a brief account of each institution, showing when it was opened, its bed capacity, the type of tuberculous patient admitted, and the names of the superintendent and the medical director. Altogether there are listed 749 institutions with 92,786 beds for tuberculous patients. This is an increase of 5,869 beds since 1934, when the previous edition of this directory was published. These figures represent beds actually in operation in April 1938, while an additional 5,126 beds are recorded as under construction or definitely provided for. New state sanatoriums have been opened in Arizona, Florida, Michigan, Mexico, New York City, North Carolina and Texas. There are now available for tuberculous patients in continental United States seventy-eight federal institutions with 8,362 beds, 399 state, county and municipal institutions with 64,042 beds, seventy-one private institutions with 3,493 beds, and 184 semi-private institutions with 13,795 beds.

Physical Therapy and Occupational Therapy Meetings.—The seventeenth annual session of the American Congress of Physical Therapy and the twenty-second annual meeting of the American Occupational Therapy Association will be held at the Palmer House, Chicago, September 12-15. The formal opening session of the congress of physical therapy will be held Monday evening September 12, with welcoming addresses by Drs. Robert H. Hayes, president of the Chicago Medical Society, and Samuel E. Munson, Springfield, president of the Illinois State Medical Society. Dr. Frank H. Krusen, Rochester, Minn., will make his official address as president of the congress on "The Contributions of Physical Therapy to Medicine" and other speakers will be Drs. Alfred W. Adson, Rochester, Minn., on "Chronic Recurring Sciatica: Diagnosis and Treatment of Ruptured Intervertebral Disks" and George Mosser Taylor, Los Angeles, "Manipulative Surgery, a Challenge to the Medical Profession." There will be a general session each day and various section meetings. The program includes symposiums on electroresection, short wave diathermy and peripheral vascular diseases. Wednesday the two organizations will hold a joint meeting at which the speakers will include Drs. Harry E. Mock, Chicago, on "Occupational Therapy in Fractures" and Francis J. Carr Jr., New York, "After-Care of Infantile Paralysis: Braces and Operations." There will also be a joint banquet Tuesday evening with Dr. Krusen as toastmaster. The speakers will include Drs. Morris Fishbein, Editor of THE JOURNAL, Chicago; Irving S. Cutter, dean, Northwestern University Medical School, Chicago, and Joseph C. Doane, Philadelphia, president of the occupational therapy association. The physical therapy congress will conduct an instruction seminar September 7-10.

HAWAII

Society News.—Dr. Edward William Alton Ochsner, New Orleans, gave a series of lectures before the Honolulu County Medical Society, May 23-June 2, on various aspects of surgery. Dr. George W. Swift, Seattle, recently discussed cerebral hemorrhages before the society.

Annual Meeting and Election.—Dr. Harry L. Arnold, Honolulu, was elected president of the Hawaii Territorial Medical Association at the annual meeting of the association in May and Dr. Douglas B. Bell, Honolulu, was reelected secretary. Guest speakers at the meeting included Drs. John L. Reichert, Chicago, on "Treatment of Gonococcal Vaginitis"; John A. Wolfer, Chicago, "Further Evidence That Pancreatic Juice Reflux May Be an Etiologic Factor in Gallbladder Disease"; Edward William Alton Ochsner, New Orleans, "Pre-operative and Postoperative Care," and William D. Sansum, Santa Barbara, Calif., "Functional Indigestion."

CANADA

Annual Meeting in Alberta.—The annual meeting of the Canadian Medical Association, Alberta Division, will be held in Calgary September 12-14. The guest speakers include Drs. Louis H. Newburgh, Ann Arbor, Mich.; John S. Coulter, Chicago; Melvin S. Henderson, Rochester, Minn.; Alfred T. Bazin, Montreal; Charles H. Hunter, Winnipeg; William A. Gardner, Winnipeg; Alfred Howard Spohn, Vancouver, and Kenneth A. MacKenzie, Halifax, president of the Canadian Medical Association. Dr. Bazin will address a public meeting on "Your Cancer Problem" and Dr. Newburgh on "Food in the Human System."

Government Services

Brigadier General for the Dental Corps

Leigh C. Fairbank, D.D.S., was recently appointed the first brigadier general in the dental corps of the U. S. Army, according to *Military Surgeon*. General Fairbank has been in charge of the orthodontic clinic at the General Dispensary in Washington for the past three years. He is a member of the American Association of Orthodontists and has been certified by the American Board of Orthodontia.

Training for Medical Reservists

The tenth annual Inactive Status Training Course for Medical Reservists of the Army and Navy will be held at the Mayo Foundation, Rochester, Minn., October 3-15. Presentation of carefully selected subjects in military medicine are scheduled and special work in clinics and hospitals will be offered during the morning hours for those asking special assignments. The last three days of the course will be merged with the annual meeting of the Association of Military Surgeons of the United States, October 13-15. All medical department reservists are eligible for enrolment. Approved applicants will be enrolled on recommendation of the surgeon of the Seventh Corps Area or the surgeon of the Ninth Naval District. Applications should be forwarded through the respective headquarters of the officer concerned.

Outbreak of Typhoid in Philippines

Eleven cases of typhoid were reported at Fort Mills, P. I., between December 29 and February 2 with two deaths, according to a recent review of the health of the U. S. Army. The outbreak was probably caused by a carrier, according to the report, since typhoid is prevalent in the native population and natives are customarily employed in the messes. This constitutes a hazard that is well recognized and all civilian food handlers are vaccinated. All these patients had been vaccinated and it could not be determined whether their infection was the result of massive doses of bacilli or of a degree of immunity insufficient to protect against small doses. The water supply at Fort Mills is unsatisfactory in many respects but has not been the avenue of transmission in any outbreak of intestinal disease. In the ten years 1928-1937 there were eighty-one cases of typhoid in the army, twenty-four of which were in the Philippines, eleven at Fort Mills. Of the cases at Fort Mills, three occurred in 1935, two in 1936, three in 1937, and one each in 1929, 1930 and 1934. One of the 1937 cases was included in the outbreak under discussion.

The Nostrum Evil

Notwithstanding repeated exposures the nostrum evil flourishes. In the House of Lords, Lord Horder called attention to the enormous growth in the quack medicine trade and the incongruity of exercising no control over the deleterious effects on health at a time when a serious effort is being made to improve national fitness. When he suggested dealing with this evil his friends said that he would have against him the vested interests of newspapers and their proprietors. It was becoming more obvious that the very head and front of the offense of quack medicines were the advertisements, so often grossly misleading if not actually fraudulent. It was said also that he would be charged with trying to create a monopoly for his profession and depriving the poor of a cheap cure. If there was any monopoly it lay with the trade that, at a cost of nearly as much as the total spent on hospital services, bled the public of between \$125,000,000 and \$150,000,000 a year. This largely unscrupulous monopoly battered chiefly on that part of the public which could least afford to feed it. If the physician thought only in terms of hard cash he would benefit by that unprincipled trade, which eventually made more patients for him.

The incongruity of the situation was obvious. On the one hand, the government had launched a campaign to improve the national physique. On the other hand, it totally failed to combat the campaign of quack medicines and foods, led by subtle and skilled generals bent on maintaining national ill health, so that they might have a ready market for their goods. For every \$500 which the government spent on making people health conscious, the nostrum venders paid \$5,000 to make them disease conscious. The group which purveyed medicines for nervous and digestive disorders budgeted nearly \$5,000,000 for advertisements alone during the coming year. In 1931 their shares stood at \$1.25; in the past three years they always stood at over \$15. A few proprietary preparations were good, and the claims made for them were reasonable as claims went. A great many that did little good or little harm were sold at fantastic prices. Now and again a remedy was sold that did definite harm. There was nothing to prevent trading in some new drug which was not on the poison schedule and concerning which experience of its action alone discovered its danger. An enormous number of preparations were fraudulent in the claims they made and the way in which these claims changed with no change in the nature of the "specific." The public was slowly learning that cancer and hernia are not cured by drugs, and advertisers were quick to realize this. People had recently become anxious about the prevalence of rheumatic disease. Straightway the venders orientated their advertisements in that direction.

Advertising had become a specialized profession. The maker of the nostrum or food handed the matter over to the advertisement specialist, with a large sum of money. The product was "put across" to the public, and there was a rake-off for both, as also for the newspaper proprietor and the advertising agent. The enormous increase in recent years of the mediums—newspapers, hoardings, busses, cinemas, wireless, post boxes and airplanes—indicated the appalling effects which that mass suggestion eventually must have on the country's health and morale. The advertisements had become a greater danger than the medicines they served to sell. Fear was the chief emotion on which they played. Not only the sick but the well were swindled. The report of the government committee on patent

medicines was printed twenty-four years ago. Its simple recommendations, registration, disclosure and censorship of advertisements, had never been implemented. Some papers were trying to control the evil by rejecting the grosser forms of exploitation, but the consequence was that they were penalized.

For the government Viscount Gage admitted that there was a case for controlling advertisements but stated it was difficult to guarantee that it would be effective. The attitude of the government would be dictated by public opinion. The difficulty was that the fault lay with the people who preferred to diagnose and treat their own ailments to using the immense state-aided medical schemes. This evasive reply is paralleled by an editorial in a leading paper, the *Daily Telegraph*. While admitting that Lord Horder has made out a strong case, it enlarges on the difficulty of devising a system of control "which shall be at once a perfect protection to the ignorant and credulous and yet not infringe legitimate interests." This comment ignores the fact that, as Lord Horder showed, the remedy is quite simple unless the paper regards fraudulent misrepresentation as a "legitimate interest."

Opening of Institute for Radiotherapy

Sir William Bragg, president of the Royal Society, opened the Meyerstein Institute of Radiotherapy at the Middlesex Hospital, the largest in the country for the treatment of cancer by radium and x-rays. It has been erected by Sir Edward Meyerstein at a cost of \$230,000. It is a compact and complete unit in which all forms of radiotherapy are available both for the inpatients and outpatients of the hospital and for private patients. There are four floors devoted to the treatment, while sixty-four beds in four wards and six private rooms house the patients who are under the care of the physicians and surgeons of the hospital. The northern half of the building is divided into treatment cubicles, all provided with duct-suction ventilation, giving a change of filtered air twelve times to the hour. The walls contain lead to prevent stray irradiation into the corridors, and the powerful tubes on the second floor have made it necessary to put lead in the floor to prevent irradiation of the patient in the cubicle below. In every cubicle there is two way communication between patient and radiographer by microphone and loud speaker. In the teleradium room mass irradiation at 8 cm. distance is carried out with 4 Gm. of radium. The transference of radium to and from the applicator head is effected pneumatically through a flexible tube, the force being provided by a vacuum device invented by the engineers of the hospital.

Sir William Bragg said that in the use of radioactivity in medicine the gap to be crossed between science and practice was of extraordinary width and the cure of malignant growths far removed from the science of atomic action, but the need for cure was so urgent that, however empiric, the treatment must be tried. On the other hand, if any understanding of the biologic processes which go wrong and of the action of radiation on them can be gained, the chances of success will be greater.

Hospital Accommodation for Air Raid Casualties

In future wars civilians as well as soldiers will have to suffer. The last of the problems which the government is attacking in a thorough way is hospital accommodation for air raid casualties. The aim is to pool hospital accommodation over a wide area and make provision for additional beds and equipment where this is necessary. Plans are also being made for moving as many as possible of the peace time sick from the hospitals best suited to deal with casualties and for transporting the casualties themselves from raided areas to those less vulnerable. Medical and other officers have been assigned to various districts in the country in order that they may maintain close contact with the local authorities and managers of

hospitals in working out schemes which can be put into immediate operation if required. In the London area a committee of experts presided over by Sir Charles Wilson, dean of St. Mary's Hospital, has been asked to advise on the special problems of a casualty organization for the metropolis.

PARIS

Protest Against Nationalization of Hospitals

In the July bulletin of the society which has charge of public relations for the physicians of Paris and its suburbs a protest is raised against a plan which was discussed at the May meeting of the French Federation of Labor. In the June 12 issue of the federation journal appears an outline of a plan according to which a national health organization termed "service for preservation of human life" is to have full control of all hospitals. There is to be a director for each of the ninety departments of France, to whom the trustees of every hospital will be responsible. The departmental director will have a number of representatives of social organizations as his aids. The secretary of the medical society of Paris and its suburbs, in his comment on this plan, states that it will give ample opportunity for politicians to secure a number of lucrative jobs for themselves and their supporters. It will also open places on the medical staffs for unscrupulous physicians who are willing to do the bidding of the newly appointed government officials who will constitute the boards of trustees of the nationalized hospitals. No doubt many men of high professional standing will continue as heads of various hospital services, but they will be considered as government officials and will have to comply with the wishes of lay directors who will be only political appointees. The professional work of high grade medical men will be judged by persons who will be incompetent to do so. As to the patients, they will lose the physician-patient relation, which has meant so much in the past, when they could be cared for in private institutions by physicians whom they had the right to choose. The general practitioner will be obliged either to enter some other profession or to accept some subordinate position in a government medical service. Of course if he accepts the latter alternative he will be obliged to work only forty hours a week, as is now the case with all officials in France. Nationalization of hospitals is being fought by the members of the medical profession here with every possible means at their disposal.

Experimental Production of Pulmonary Air Embolism

At the June 10 meeting of the Société médicale des hôpitaux of Paris the results of an experimental study of air embolism were reported by Prof. Maurice Villaret and Dr. René Vachera. They stated that formerly air embolism was of interest only as a complication of operations, but on account of the rapidly increasing number of artificial pneumothorax treatments of pulmonary tuberculosis the subject was of great interest to internists. The authors employed for the first time a technic in which the entrance of air into the cerebral vessels could be observed microscopically. They combined this method with introduction of air into the pulmonary veins. It was found, first, that in nine of ten experiments air embolism of the cerebral vessels appeared immediately after entrance of air into a pulmonary vein; second, that relatively small amounts of air, 5 cc. in some experiments and from 10 to 20 cc. in others, sufficed to produce cerebral air embolism; third, that simple puncture of a pulmonary vein as the result of a spontaneous aspiration of air was followed by a massive air embolism of the brain and death, and, fourth, that the general circulatory reactions were minimal, in the form of a slight increase of blood pressure.

The question arises whether or not the pulmonary circulation offers any resistance to the entrance of air. In eleven of thirty-two animals, or 34.3 per cent, the air passed beyond the pulmonary barrage. This passage took place slightly more often in dogs than in rabbits, whether anesthetized or not. When the air passed into the pulmonary veins its entrance could easily be verified.

Injection of air into a pulmonary vein is followed by very rapid respiration if the embolism is minimal or moderate and by apnea if a large amount of air has entered. The heart continues to beat for some time. The fall in blood pressure is very marked and immediate. Even the injection of from 30 to 50 cc. of air into a pulmonary vein is followed by a drop in blood pressure to zero. The cerebral symptoms are either dependent on those of the respiratory and cardiovascular systems or independent of them in the form of focal lesions such as hemiplegia, which may be of only a few hours' duration.

The Secretion Test of Pancreatic Function

In an article which appeared in the *Presse médicale* for March 14, 1936, attention was called by Chiray and Bolget to a test of pancreatic function which enables the clinician to differentiate icterus due to insufficiency of the external secretion of the pancreas from icterus due to hepatic causes or to obstruction of the extrahepatic ducts. At the June 24 meeting of the Société médicale des hôpitaux, a case was reported by Dr. Jean Cathala and his associates which confirms the value of this secretion test. The patient was a boy aged 12 with a history of intense icterus of two months' duration with alternation of acholic and bile-stained stools. The pancreatic origin of the icterus was definitely shown by three negative provoked-galactosuria tests, which indicated that the liver functioned normally although it was shown by palpation and plain roentgenograms to be greatly enlarged. The secretin test revealed a marked decrease in the functional activity of the pancreas. The boy had lost a great deal of weight, but as soon as he was given dextrose by the drop method rectally, kept in bed and placed on a strict diet he began to gain weight rapidly and the stools ceased to be alternately acholic and bile stained. These clinical evidences of returning pancreatic external secretion were confirmed by repeated secretin tests revealing a normal trypsin activity. This was not true of the lipase secretion, which was much slower in returning, as shown by the secretin tests. During over four months of observation the liver gradually assumed its normal size, and only a slight sub-icteric hue persisted.

Program of 1938 French Medical Congress

This year's French Medical Congress will take place September 26-28 at Marseilles. It is the custom in all French national societies to select by vote at the preceding annual meeting certain subjects and to assign two or three members to make a critical analysis of the literature and, after adding their personal experience, to submit a report at the next congress. On the first day a report will be read on icterospirochetosis, on the second day one on hypochloremias, and on the third day one on the treatment of avitaminoses in adults. American physicians who desire further information are asked to write to Prof. Henri Roger, 66 boulevard Notre Dame, Marseilles.

A congress on renal insufficiency will be held September 22 at the health resort Evian on the French side of Lake Geneva.

International Congress of Examiners for Insurance Companies

The International Congress of Examiners for Insurance Companies will be held May 18-20, 1939, at Paris. The honorary presidents are Dr. P. Hornig of Berlin and Sir Walter Langdon-Brown of London. The president is Prof. M. Loeper of Paris. Papers will be read on the influence of pulmonary

tuberculosis, hyperthyroidism, obesity, tobacco and albuminuria on life expectancy. A series of papers will also be read on the value of vital statistics in life insurance. Dr. Wireman Cook of Minneapolis will take part in the last-named symposium. Inquiries regarding the congress can be sent to Dr. P. A. Carrier, 8 rue de Belloy, Paris, 16*.

BERLIN

July 7, 1938.

The Campaign Against Epidemic Poliomyelitis

Dr. Ernst Meier of the National Health Bureau has had published a report on epidemic poliomyelitis in the German reich. The morbidity of the disease in Germany has always remained within moderate bounds. This circumstance is explicable on various grounds: widespread immunity granted by unrecognized infections, high incidence of abortive forms, and so on. The tendency of the statistical figures for poliomyelitis to remain rather low is based on the following circumstance: Since the disease in epidemic form usually is confined to a geographically circumscribed area, the morbidity for a very large area such as Germany tends to remain moderate, in contrast to the frequently high local rates; in smaller countries, on the other hand, epidemics of the same magnitude can send the national morbidity soaring. Besides, in certain parts of the world, in Sweden, for example, and in northern sections of the United States, a special and inexplicable danger from poliomyelitis is present. Recently a high incidence of the disease has been manifested in Germany. The two years which witnessed the most serious outbreaks of poliomyelitis since the war were 1927, with 2,840 cases, and 1932, with 3,869 cases. After a notable recession in 1933, the number of cases has again risen, as the accompanying table shows. The figures do not necessarily signify a permanent tendency to increase; during the five years following the 1927 epidemic a similar upward trend was observable.

The morbidity of epidemic poliomyelitis for the German reich in 1937 was 4 per hundred thousand of population; the highest national morbidity recorded in recent years was 6, in 1932. Still greater are the differences in morbidity as between

Epidemic Poliomyelitis in Germany

Year	Cases
1933.....	1,251
1934.....	1,699
1935.....	2,080
1936.....	2,256
1937.....	2,723

various countries. For example, in 1936 the morbidity per hundred thousand of population was 1.4 for England and Wales, 3.4 for the German reich and 49 for Sweden. How significant the geographic delimitation of epidemics may be for such figures is exemplified by the fact that whereas in upper Bavaria in 1937 the morbidity was 41.3 (still per hundred thousand of population), that of the entire reich in the same year was, as mentioned, only 4. These local variations, as numerous examples attest, play an important part in the statistics of poliomyelitis, and if the statistics are incomplete false conclusions are easily arrived at.

An exact analysis shows that in 1936 a certain displacement in the morbidity took place in the direction of the higher age group and that this trend continued during 1937. In Berlin and Munich more cases were reported among older female groups than among older male groups.

The inauguration of special measures on the part of the federal health authorities is justified by the severe sequels of poliomyelitis, although the disease in its most severe form is not frequent. Observations made in Germany in recent years

permit one to estimate roughly that, of one million children born in a certain year, 2,000 are effected with poliomyelitis in the course of their youth. Of these, 600 recover completely, 1,200 remain crippled and 200 die of the disease. Hopes for successful therapy of poliomyelitis have in recent years been centered in convalescent serum, which was first extensively administered in Germany in 1932 and which subsequently has come to be generally utilized. Although successful results were not always observed after use of this serum, this therapeutic method enjoys a high reputation in Germany. On the one hand, favorable-sounding results are reported but, on the other hand, there is no truly successful therapeutic method. The distribution of serum necessitated the formation of a special type of organization, which has now been functioning efficiently for several years. On account of the surprisingly high

Convalescent Blood Received at Behring Laboratories

Year	Liters of Blood
1934.....	70
1935.....	150
1936.....	90
1937.....	166

local incidence of the disease, central assembly of the serum has been found expedient. Nationwide distribution is centered in the National Health Bureau, which sedulously observes the course of an epidemic (by following current medical reports) and plans the necessary measures to be taken. The available supplies of serum are always carefully regulated. In general the abstraction of blood takes place from May forward; namely, a short while before the period of seasonal epidemics. All organizational difficulties have been solved, and the cooperation of health officials everywhere is assured. A special campaign of propaganda to augment the ranks of suitable blood donors has been initiated. In all Germany only two establishments engage in preparation of the serum: the Behring Laboratories, Marburg, supply the entire reich excepting Saxony, and Saxon Serologic Laboratories, Dresden, supply that province. The quantities of convalescent blood received at the Behring Laboratories in recent years are listed in the accompanying table. The figures for 1935 and 1937 are higher, as concerted campaigns for the assembly of convalescent blood took place in each of those years. Furthermore, a special method of prompt reporting has been instituted in order that foci of infection may be isolated.

Of further interest is the author's investigation of the time required for recognition of poliomyelitis. A study of 600 cases disclosed that the elapsed time between the onset of the illness and the beginning of treatment was more than one week in 14.3 per cent, that treatment was begun on the very day the patient became ill in only 17.7 per cent and that about half (50.9 per cent) of the patients first received medical attention within two days after the onset of illness. For the prognostic evaluation of convalescent serum it is important to realize that in about half the cases the physician did not see the patient before the fourth day of illness. A factor that makes for this delay, in addition to difficulties of transportation in certain regions, is the vagueness of the initial symptoms, which often causes the parents of a stricken child to put off seeking the physician. Throughout the German reich cases of epidemic poliomyelitis must be reported to the health authorities by the attending physician. In 14.6 per cent of the 600 cases the report was made on the first day of treatment; in 13.8 per cent it was not made for more than a week after treatment was begun, and in the vast majority of cases (52.7 per cent) it was made on the second day of treatment. The late reports may be considered as due chiefly to the main difficulties of diagnosis. During epidemics cases tend to be reported at an earlier stage, as is readily understandable.

Prof. Hermann Straub Is Dead

Prof. Hermann Straub, Göttingen ordinarius of internal medicine, died suddenly at the age of 55 while on a professional journey. Straub was a pupil principally of Professor von Romberg; in addition he received excellent training in physiology and pharmacology at Freiburg, Cambridge and London. After serving for many years as senior physician of the First Medical Clinic, Munich, he was called to Halle, at the age of 36. Subsequently he served at Greifswald and for the past decade had been at Göttingen. Straub was one of the foremost authorities on diseases of the circulation, a field to which his minutely elaborated clinical and experimental work contributed much. Among his publications may be mentioned those on the determination of blood pressure, on examinations of the dynamics of pulsation, on velocity of the blood current and cardiac beat volume, and on determination of pressure in the different cavities of the heart. His factual exactitude earned him a great reputation.

BUCHAREST

June 25, 1938.

Syphilis in Rumania

Dr. G. Banu, formerly minister of health in Rumania, made extensive investigations of syphilis in Rumania. In the province of Transylvania syphilis has a long history. Krauss found syphilitic patients in Brasov in 1500. About the end of the eighteenth century there were epidemics of syphilis. The frequent wars during the rule of the Hapsburgs and the movements of troops were responsible for the general high incidence of syphilis in the Banat. It is recorded that at the end of the eighteenth century Maria Theresa removed all prostitutes from Vienna and settled them in the environment of Timisoara, in places where the majority of the population were Rumanians. By this measure syphilis was spread to such an extent that hospitals had to be erected for the treatment of this one disease in Comoraste village, Lugoj, Faget and Caransebes.

The first records of syphilis in the Rumanian principalities go back to the seventeenth century, when prostitution was extensive in Bucharest. As contact was made with the neighboring states, syphilis spread, chiefly imported by the rich landowners who used to go abroad. At the commencement of the nineteenth century a new focus of infection was formed by the Russian army. In 1835 syphilis claimed many lives in Bucharest, Arges and Teleorman. The administrative board of Muntenia passed the following resolution Aug. 21, 1843: "Since venereal disease has come to our country, all public women should be secretly conscribed, and at a certain place on a certain day in a certain hour they shall be collected and examined; those found sick are to be sent to the hospital." In 1844 the Coltea and Pantelimon hospitals had 227 women patients suffering from venereal diseases. In Moldavia systematic control of the prostitutes was introduced in 1844. They were registered by the police and given a booklet in which weekly medical examinations were recorded, and those found sick were sent to the hospital. In Bucharest a similar regulation was introduced in 1862. Legislation dealt with the problem of syphilis in 1874, 1886 and 1898.

Of conditions prevailing about the end of the past century Professor Felix writes: "In the last decades of the nineteenth century the lowered morals, the increase in the number of bachelors, the ever growing luxury, the introduction of compulsory military service and the excessive formalities demanded by notary publics with a decrease in the number of marriages all promoted the spread of venereal diseases." In 1898 and 1899 the total number of syphilitic patients treated in all hospitals of the country was about 10,000 yearly, while in the outpatient departments of hospitals the attendance amounted to 28,000. According to the data supplied by Bordea there were 9,563

syphilitic persons in 1901, 9,595 in 1905 and 11,651 in 1915. The number increased from 1918 on, which can be attributed chiefly to the enlargement of the country's territory by the addition of Transylvania, Bessarabia and the Banat. There were 14,067 patients on record in 1918, 22,485 in 1919 and 30,509 in 1920. The increasing number is due not so much to the spread of the disease as to intense activity in the finding of cases. These figures do not include all syphilitic persons in the country, for many patients seek relief from private physicians. As to the capital city itself, 2,605 patients were attended in Bucharest in 1910, 3,530 in 1915, 3,632 in 1918 and 2,738 in 1920. These figures also do not show the true conditions. For instance, in the Eufforia Hospital, where free outpatient service is given, in one year there was a turnover of 13,942 patients with venereal disease, and among these were many with syphilis.

Conditions in Transylvania are reflected by the statistics compiled by the antivenereal disease dispensaries, according to which 1,307 syphilitic patients received treatment in 1919 and 2,111 in 1920. In Transylvanian hospitals 6,188 syphilitic patients were under medical care in 1919 and 8,818 in 1920.

The World War was a large factor in the spread of syphilis. In both territories of Rumania, that which was occupied by the enemy and Moldavia, which was overrun by the Russians, the number of persons with syphilis increased. The spread of syphilis was promoted much more by the Russian than by the Austro-Hungarian or the German army.

A report states that in 1928 there were 146,707 persons with syphilis, of whom 89,691 were subjected to treatment; that is, 61 per cent. The number of doses of neoarsphenamine used that year in free dispensaries was 651,982. The morbidity per hundred thousand of population was 843.5. The percentages of the forms of syphilis were as follows: primary 10.7, secondary 34.4, tertiary 13.3, latent 29.6, parasyphilis 2.9 and heredo-syphilis 9.1 per cent. The mortality rate per thousand patients was 9. It is distressing that according to these statistics a great number of patients receive no treatment.

With reference to the sexes, the infected males represented 47.2 per cent and the women 52.8 per cent. The most infected province is the old kingdom, the rate being 1,097 per hundred thousand of population; then follow Bucovina, Bessarabia and Transylvania. This state of affairs in the old kingdom is due to cultural, social and political conditions and invasion during the war. In Bucovina the reported number of syphilitic persons is higher than in Bessarabia, because in Bucovina the case-finding campaign was carried on with much greater energy.

It is causing great anxiety that 10.7 of 100 syphilitic persons suffer from primary and 34.4 from secondary syphilis, as almost half of the syphilitic population is in the infectious stage. The social peril in this situation worries the leaders of public health, who will endeavor to stop the spread of infection by strict control, compulsory notification, forced treatment and lectures to the public.

The Care of Mothers and Children

The ministry of health intends to erect a school of midwifery in every great urban center to make possible the ideal that every village shall have its own midwife. In the schools of midwifery pupils will be admitted only from the surrounding country and after studying for one year they will be given the right to practice midwifery, but only in villages. The midwife will not get a fixed salary from the village but will be paid by the state according to how many births she attends. In this way it will be to her interest that the number of births in the village shall be as many as possible and so she will refuse to help gravid women get rid of their burden.

Experience in the field of child welfare has shown that the high infant mortality in the rural districts is attributable first to lack of knowledge necessary to the nursing of children under 1 year of age. The ministry of health contemplates

establishing many more village dispensaries, provided with matrons, whose chief duty will be the elimination of some bad customs existing in some villages and the changing of the nursing and care of infants in the right direction.

ITALY

(From Our Regular Correspondent)

June 30, 1938.

Meeting of Urologists

When the Società di Urologia recently met at Naples, Professor Cacchi of Padua reported studies performed on thirty-three strains of tubercle bacilli which were isolated from the urine in cases of human renal tuberculosis. The identification was made by the cultural properties of the several strains on elective culture mediums, such as Petragani's, with 3 per cent glycerin. The biologic test was also made. In three of the thirty-three cases the isolated strain presented the characteristics of the bovine type. The speaker discussed the symptoms and the evolution of the condition in these three cases, all of which were grave and two of which were rapidly fatal.

Dr. Bravetta of Milan called attention to the canalization of urinary calculi which are situated along the secretory route of the kidney. Dr. Di Maio of Milan, who from 1932 has studied the pathologic conditions which develop in workers who handle amines, reported his observations in 1937. There was a case of malignant tumor of the bladder, one of primary benign papilloma, two recurrences of benign multiple papilloma and fifteen cases of precancerous congestion.

Dr. Garofalo of Bologna spoke on a sign of cancer of the prostate. In the last two years he has observed nineteen cases of neoplasm of the prostate in patients ranging in age from 50 to 80 years. The diagnosis was confirmed in seven cases by microscopic study and in the other twelve by the clinical evolution of the condition. In 50 per cent of the cases the deferent canals were uniformly dilated to the caliber of a No. 15 Charrière sound. The other parts of the structure were normal. The sign of the deferent canal is frequent in young patients suffering from solid carcinoma of the prostate. It does not show when the condition is adenocarcinoma or the patient is over 70. According to Dr. Garofalo the changes of the deferent canal are due to hypertrophy of the muscular layers of the canal from effort during passage of the spermatic current through the ejaculatory ducts which are compressed by the tumor. The sign is of clinical importance.

Dr. Pellicchia stated that the development of adenoma depends on the presence of organic and humoral modifications related to the age of the patient. The endocrine theory is not enough to explain the formation of adenoma. The speaker said that endocrine hyperfunction from old age and the diminution of sexual functions may be the factor for the production of adenoma. He reported satisfactory results from the administration of sex endocrine products. In cases of acute retention of urine the glandular treatment induced voluntary micturition. In all cases the treatment is harmless. Dr. Oberholtzer reported his results from a treatment with synthetic testis hormones or with testicular extracts in a group of fifty patients suffering from prostatism. The subjective symptoms improved in all cases. In cases of chronic retention of the urine, reduction or complete disappearance of the residue took place. In several cases of complete retention the treatment induced voluntary micturition. The speaker said that the treatment with testis hormones has to be administered as soon as the disorders of micturition appear.

International Congress of Criminology

The first International Congress of the Society of Criminology will meet at Rome late in September. The following topics of discussion appear on the agenda: Etiology and Diagnosis of Juvenile Criminality; Data on Certain Legal Procedures; Per-

sonality Study of the Delinquent; Role of the Judge in the Anticrime Campaign; His Criminologic Training; Organization for Prevention of Crime in Various Countries; Ethnology and Criminology; Practical Application of Public Safety Measures in Various Countries.

Obligatory Insurance Against Tuberculosis

The Council of Ministers recently passed a law by which insurance against tuberculosis is obligatory to all school teachers and didactic directors who make a monthly salary of more than 800 lire (\$40). Sons, brothers and sisters under the age of 21 who are supported by the insured person will receive the benefits of the insurance. The money necessary for expenses will be collected by means of an annual tax of 36 lire for each insured person.

Professor Di Vestea is Dead

Prof. Alfonso Di Vestea, who for thirty-eight years occupied the chair of hygiene at the University of Pisa, died at Rome. Among the best known and most important of his accomplishments were his studies of the virus of rabies and its filtrability, the climatotherapy of tuberculosis, the methods of microscopic examination of different types of flour and, in addition, much experimental work in the most diversified fields of hygiene and of microbiology. Di Vestea founded the first antirabies institute in Italy, at the medical clinic of Naples. He was author of a manual of school hygiene that has become classic. He was also a propagandist of child welfare, particularly with regard to the organization of open air colonies for children in the mountains and at the seashore.

Marriages

WENDELL HOLMES COOK, Philadelphia, Miss., to Miss Jane Elizabeth Peneguy in New Orleans, June 26.

JAMES NEWBURN BURCH, Shelbyville, Tenn., to Miss Sara McQuiddy Cortner at Bell Buckle, May 28.

HARRY CARRINGTON FLEMING, New York, to Miss Evelyn Brooks in Charlottesville, Va., July 2.

LUCILLE MARY BOND, Toronto, Ont., Canada, to Mr. Albert Henry Kraft of New York, June 27.

LESLIE HOMER BACKUS, Gloversville, N. Y., to Miss Helen Torrey Grant in Northville, July 2.

LOUIS PHILIP BAILEY, Nathalie, Va., to Miss Telia Barner Barksdale in Sutherland, June 18.

JOHN BARTON BURRETT, New York, to Miss Clara Theodora Bray of Orlando, Fla., July 2.

KENNETH H. BROWN, Indianapolis, to Miss Rosamond Hoagland of Decatur, Ill., July 1.

VERNON DUANE THYSELL, Hawley, Minn., to Miss Nanette Abt of Minneapolis in June.

BRADFORD CANNON, St. Louis, to Miss Ellen DeNormandie of Lincoln, Mass., recently.

WILLIAM J. BAILEY to Mrs. Lucille H. Durden, both of Fort Lauderdale, Fla., June 16.

JOHN WILLIAM BALLOU, Rushville, Ill., to Miss Marijane Corya in Denver, July 9.

ALBERT HENRY ANDREWS JR., Chicago, to Miss Jane Olson of Oak Park, Ill., June 25.

CHARLES M. CLENDENEN to Miss Helen Boucher, both of Damascus, Va., in June.

ALMON R. CROSS, Durham, N. C., to Miss Doris Ellen Brown of Goldsboro, June 5.

MARK P. VIRNIG, Wells, Minn., to Miss Genevieve Kelly of Minneapolis, June 20.

JOHN CANNON, New York, to Miss Jean Carter of Huntington, N. Y., June 25.

EARL WILLIAM ELLIS, Elgin, Minn., to Miss Marvel Wagner of Shafer, recently.

WILLARD MANVILLE AKINS, Eveleth, Minn., to Miss Lila Koivisto, recently.

CLIFFORD HERBERT BRUSH to Miss Mary Moffitt, both of Chicago, June 25.

Deaths

Frederick Peterson • Bridgewater, Conn.; University of Buffalo School of Medicine, 1880; chairman of the Section on Neurology and Medical Jurisprudence, American Medical Association, 1898-1899; professor of pathology at his alma mater, 1882-1884; professor of nervous and mental diseases, University of Vermont, 1888-1889; professor of psychiatry, Columbia University College of Physicians and Surgeons, 1903-1915; member and past president of the American Neurological Association; member of the American Psychiatric Association, Association for Research in Nervous and Mental Diseases and the American Psychopathological Association; president of the New York State Commission in Lunacy, 1901-1904, and the New York Neurological Society, 1899-1901; since 1894 member of the board of managers, Craig Colony, Sonoma, N. Y., and at one time president; at various times alienist to Bellevue Hospital, and to the Manhattan, Flatbush, and Central Islip State hospitals; co-editor of a two volume work, "Legal Medicine and Toxicology" and "Atlas of Legal Medicine," translated from the German; co-author of nine editions of "Nervous and Mental Diseases"; contributed numerous articles to various magazines; received honorary degrees from University of Niagara in 1888 and the University of Pennsylvania in 1919; aged 79; died, July 9, in New York of diabetes mellitus.

Homer Gage • Worcester, Mass.; Harvard University Medical School, Boston, 1887; member of the American Surgical Association; past president of the New England Surgical Society; fellow of the American College of Surgeons; served during the World War; for many years medical director of the State Mutual Life Assurance Company; past president of the Association of Life Insurance Medical Directors of America; member of the board of overseers, Harvard University, 1921-1927, 1928-1934; trustee, Worcester Polytechnic Institute, 1907-1938, and treasurer, 1908-1938; on the consulting staff of the Worcester City Hospital; on the consulting medical board of the Memorial Hospital and president of the board of trustees; aged 76; died, July 3, of coronary thrombosis.

John Bromham Hawes II • Boston; Harvard University Medical School, Boston, 1903; president of the Boston Tuberculosis Association; member of the American Clinical and Climatological Association; formerly assistant visiting physician and director of the clinic for pulmonary diseases, Massachusetts General Hospital; director of the Rutland (Mass.) Cottage Sanatorium; consultant, diseases of the lungs, U. S. Veterans' Bureau; co-author, with Dr. M. J. Stone, of "Diagnosis and Treatment of Pulmonary Tuberculosis"; author of "Early Pulmonary Tuberculosis," "Tuberculosis and the Community," and others, and of numerous monographs on pulmonary diseases; aged 61; died, July 20, of coronary occlusion.

Henry Valentine Broesser • Hoboken, N. J.; New York Homeopathic Medical College, 1900; member of the Radiological Society of North America; member of the county board of health; served during the World War; on the staffs of St. Mary's Hospital, Hoboken, St. Francis Hospital, Jersey City, and the North Hudson Hospital, Weehawken; aged 69; died, June 29, of arteriosclerosis and acute cardiac dilatation.

Samuel Frank Abrams • St. Louis; Washington University School of Medicine, St. Louis, 1917; member of the Central Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; aged 46; visiting gynecologist to St. Louis City Hospital and associate gynecologist and obstetrician to the Jewish Hospital, where he died, June 26, of thrombosis.

George Bertram Booth, Los Angeles; Toledo Medical College, 1907; member of the Ohio State Medical Association; fellow of the American College of Surgeons; served during the World War; formerly surgeon to the Mercy Hospital and on the advisory staff of the Lucas County Hospital, Toledo; aged 57; died, June 8, in the Veterans Administration Facility, West Los Angeles.

Leon Emile Duval, Ionia, Mich.; University of Vermont College of Medicine, Burlington, 1915; member of the Michigan State Medical Society and the American Psychiatric Association; assistant superintendent of the Ionia State Hospital; aged 46; died, June 17, of burns received when he poured gasoline over his automobile and clothing and set them on fire.

Victor Dryden Holloway • Knoxville, Tenn.; University of Pennsylvania Department of Medicine, Philadelphia, 1907; member of the Southeastern Surgical Congress; fellow of the American College of Surgeons; surgeon to Fort Sanders and St. Mary's Memorial hospitals; gynecologist to the Knoxville General Hospital; aged 53; died, June 24, of leukemia.

Samuel Griggs Jett, Reidsville, N. C.; University of the South Medical Department, Sewanee, Tenn., 1903; member of the Medical Society of the State of North Carolina; health officer; formerly county coroner; member of the local school board; aged 57; died, June 11, in the Memorial Hospital, Danville, Va., of coronary thrombosis.

Levi S. Walton, Jenkintown, Pa.; Jefferson Medical College of Philadelphia, 1885; member of the Medical Society of the State of Pennsylvania; past president of the Bucks County Medical Society; formerly a member of the U. S. Board of Pension Examiners; aged 75; died, June 8, of coronary thrombosis.

Susan Jones, Racine, Wis.; Rush Medical College, Chicago, 1903; member of the State Medical Society of Wisconsin; past president and secretary of the Racine County Medical Society; aged 75; died, June 17, in St. Mary's Hospital, of coronary thrombosis, diabetes mellitus and arteriosclerosis.

Samuel Chester Eveleth • Marblehead, Mass.; Harvard University Medical School, Boston, 1908; chairman of the school board; on the staff of the Mary A. Alley Emergency Hospital; aged 55; died, June 13, of coronary thrombosis, cerebral hemorrhage, pneumonia and empyema.

Waheeb Salem Zarick, Indianapolis; Indiana University School of Medicine, Indianapolis, 1927; member of the Indiana State Medical Association; assistant professor of anatomy, Indiana University School of Dentistry; public schools physician; aged 46; died, June 28.

Matt S. Dibrell, Van Buren, Ark.; Arkansas Industrial University Medical Department, Little Rock, 1889; member of the Arkansas Medical Society; past president of the Crawford County Medical Society; aged 71; died, June 1, of hypertension and heart disease.

Myron Joseph Fox, Waterbury, Conn.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1928; member of the Connecticut State Medical Society; aged 38; died, June 28, in the Massachusetts General Hospital, Boston, of heart disease.

Edward Everett Green • New York; Long Island College Hospital, Brooklyn, 1906; served during the World War; on the staff of the Swedish Hospital; aged 69; died, June 30, in the Brooklyn Hospital of arteriosclerosis and coronary occlusion.

John William Pinkert, Louisville, Ky.; Southwestern Homeopathic Medical College and Hospital, Louisville, 1896; formerly associate professor of anatomy at his alma mater; aged 73; died, May 3, of carcinoma of the stomach and liver.

Harry William Vickers • Little Falls, N. Y.; Cornell University Medical College, New York, 1903; served during the World War; on the staff of the Little Falls Hospital; aged 61; died, June 11, of carcinoma of the kidney with metastasis.

Frank Fred Hoffmann • Chicago; Bennett College of Eclectic Medicine and Surgery, Chicago, 1901; on the staffs of the Illinois Masonic Hospital and the Norwegian-American Hospital; aged 59; died, June 22, of coronary occlusion.

Kenneth Beymer Turner, Los Angeles; Columbian University Medical Department, Washington, D. C., 1902; aged 62; died, May 27, in the Veterans Administration Facility of cirrhosis of the liver and arteriosclerotic heart disease.

Walter Duke Ellis, Plano, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1894; member of the State Medical Association of Texas; aged 69; died, June 14, in the Baylor Hospital, Dallas, of cirrhosis of the liver.

Albert Field Groves, Daytona Beach, Fla.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1879; aged 84; died, June 22, in the Halifax District Hospital of myocarditis and nephritis.

Mack Henry Tabor, Crumpler, W. Va.; University College of Medicine, Richmond, 1910; member of the West Virginia State Medical Association; formerly member of the state legislature; aged 52; died, May 16.

Paul Roy Jones, Mobile, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1898; aged 61; died, June 14, at his home in Whistler of cirrhosis of the liver, chronic myocarditis and chronic sinusitis.

Henry W. Schrock, Lagrange, Ind.; Cincinnati College of Medicine and Surgery, 1881; member of the Indiana State Medical Association; aged 83; died, June 3, of influenza, pneumonia and heart disease.

Ida Johanna Heiberger, Washington, D. C.; Woman's Medical College of Pennsylvania, Philadelphia, 1885; aged 80; died, June 15, in St. Elizabeth's Hospital of acute left hemiplegia and arteriosclerosis.

Charles Ray Dever, Hastings, Neb.; Ensworth Medical College, St. Joseph, Mo., 1911; member of the Nebraska State Medical Association; aged 57; died, May 25, in St. Joseph, Mo., of carcinoma of the prostate.

Ryan Alfred Gyles, Blackville, S. C.; University of Maryland School of Medicine, Baltimore, 1891; formerly mayor; at one time member of the state legislature; aged 67; died, June 26, of coronary occlusion.

Henry Harbaugh Rhodes Ⓢ Middletown, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1902; member of the board of health; aged 63; died, May 24, of arteriosclerosis and cerebral hemorrhage.

Frank Scofield Skemp, Talihina, Okla.; Minneapolis College of Physicians and Surgeons, 1909; member of the Oklahoma State Medical Association; aged 54; died, June 6, in Denver, of myocarditis.

Fletcher J. Wright Ⓢ Petersburg, Va.; University College of Medicine, Richmond, 1899; member of the state board of medical examiners; on the staff of the Petersburg Hospital; aged 65; died, May 8.

Edward William Tisdale, Los Angeles; University of Louisville (Ky.) Medical Department, 1893; member of the State Medical Association of Texas; aged 75; died, May 14, of chronic myocarditis.

Arthur A. Hobbs, Kansas City, Mo.; Kansas City Medical College, 1896; member of the Missouri State Medical Association; served during the World War; aged 70; died, June 7, in St. Joseph Hospital.

John Caldwell Decker, Portola, Calif.; Cooper Medical College, San Francisco, 1904; formerly county health officer; served during the World War; aged 61; died, May 13, of coronary occlusion.

William Edward O'Connor, Omaha; Creighton University School of Medicine, Omaha, 1936; aged 27; resident at Henry Ford Hospital, Detroit, where he died, June 7, of a self-inflicted bullet wound.

Charles Morlan Hole Ⓢ Cleveland Heights, Ohio; Western Reserve University Medical Department, Cleveland, 1898; aged 69; died, June 16, in a hospital at Cleveland of arteriosclerotic heart disease.

Frank Amasa Hodgdon, Malden, Mass.; Hahnemann Medical College and Hospital, Chicago, 1886; aged 81; died, June 18, of complications resulting from a broken leg suffered in a fall.

Henry Lewis Hille, Collinsville, Okla.; Hospital College of Medicine, Louisville, Ky., 1904; president of the school board and formerly mayor; aged 57; died, May 31, of heart disease.

George Franklin Stack, Superior, Wis.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1896; aged 68; died, June 2, of arteriosclerosis and heart disease.

Edward Clinton Davis, Milwaukee; Bennett College of Eclectic Medicine and Surgery, Chicago, 1914; aged 48; died, June 16, of coronary sclerosis and carcinoma of the rectum.

Theodore Young Hull Ⓢ San Antonio, Texas; Columbian University Medical Department, Washington, D. C., 1892; aged 77; died, June 30, of hemorrhage into the pons-oblongata.

Flora Pollack, Baltimore; Woman's Medical College of Baltimore, 1891; member of the Medical and Chirurgical Faculty of Maryland; aged 72; died, May 27, of mitral stenosis.

Gardiner Spring Jr., Salisbury, Md.; Medical College of Virginia, Richmond, 1913; aged 47; died, June 28, in the Johns Hopkins Hospital, Baltimore, of tuberculosis of the lungs.

Peter Charles Schenkelberger Ⓢ Chicago; Hahnemann Medical College and Hospital, Chicago, 1903; aged 59; was killed, June 26, when he fell from a nine story window.

Eugene J. Bittman, Los Angeles; Washington University School of Medicine, St. Louis, 1897; aged 64; died, May 21, in the California Hospital of acute coronary thrombosis.

Frank Edward Mahoney, New Stanton, Pa.; University of Pittsburgh School of Medicine, 1932; aged 30; died, May 10, in the University Hospital, Philadelphia, of leukemia.

Marshall Dayton Hamner, Hannibal, Mo.; University of the City of New York Medical Department, 1877; aged 82; died, June 8, in the Levering Hospital of prostatitis.

John B. Booz, Pittsburgh; University of Pittsburgh School of Medicine, 1908; member of the Medical Society of the State of Pennsylvania; aged 57; was drowned, June 1.

Charles C. Van Valkenburgh, Fresno, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1878; aged 88; died, May 12, of arteriosclerosis.

Wilfred Everett Bixby, Sebastopol, Calif.; University of California Medical Department, San Francisco, 1907; aged 55; died, June 29, of a self-inflicted bullet wound.

Joseph Peters Hershberger, Lancaster, Ohio; Hahnemann Medical College of Philadelphia, 1881; aged 82; died, June 11, of cerebral hemorrhage and arteriosclerosis.

Charles Morris Simpson, Cleveland; Beaumont Hospital Medical College, St. Louis, 1890; aged 78; died, June 7, in the Fairview Hospital of coronary thrombosis.

Frederick Barber Meek, Oklahoma City; Western University Faculty of Medicine, London, Ont., Canada, 1901; aged 65; died, June 22, of coronary thrombosis.

John Joseph Wenzke, Celina, Ohio; Ohio State University College of Medicine, Columbus, 1929; aged 35; died, May 31, in Howard, Pa., of pulmonary tuberculosis.

Joab Langston Thomas, Bessemer, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1921; aged 45; died suddenly, June 8, of angina pectoris.

Kenneth W. Sneed Ⓢ Wortham, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1892; aged 68; died, June 26, of cerebral hemorrhage.

Sumner Bradbury Marshall, Alfred, Maine; Medical School of Maine, Portland, 1898; aged 67; died, June 1, in a hospital at Sanford, of pneumonia.

Samuel Smith, Boston; St. Louis College of Physicians and Surgeons, 1924; member of the Massachusetts Medical Society; aged 45; hanged himself, June 20.

Carl Walmer Moffitt, Rockland, Maine; Hahnemann Medical College and Hospital of Philadelphia, 1894; aged 69; died, May 25, of chronic myocarditis.

Charles Card Selden, Oberlin, Ohio; Long Island College Hospital, Brooklyn, 1895; aged 77; died, June 15, of arteriosclerosis and coronary thrombosis.

Greenbery Kates Talley, Tyler, Texas; Louisville (Ky.) Medical College, 1890; Missouri Medical College, St. Louis, 1894; aged 79; died, April 19.

Andrew Jefferson Hoover, Wynne Wood, Okla.; Jefferson Medical College of Philadelphia, 1887; aged 77; died, June 22, of cerebral hemorrhage.

James William Aitchison, Madrid, N. Y.; New York University Medical College, 1896; for many years health officer; aged 75; died, May 11.

William Edmond Anderson, Lake Alma, Sask., Canada; Queen's University Faculty of Medicine, Kingston, Ont., 1910; aged 67; died, May 13.

James Harlan Wells, Shell Rock, Iowa; State University of Iowa College of Medicine, Iowa City, 1902; aged 80; died, May 27, of atheroma.

Sarah Hughes Graves Cornell, San Francisco; Cooper Medical College, San Francisco, 1892; aged 75; died, May 13, of coronary sclerosis.

James R. Autrey, Columbus, Ark.; Louisville (Ky.) Medical College, 1889; member of the Arkansas Medical Society; aged 79; died, June 17.

George Elbert Hall, Alamo, Calif.; California Eclectic Medical College, Los Angeles, 1898; aged 65; died, May 3, of diabetes mellitus.

Asa Vernon Snow, Cushman, Mass.; Bellevue Hospital Medical College, New York, 1879; aged 80; died, June 8, of heart disease.

Alton Jeffries, Detroit; Michigan College of Medicine and Surgery, Detroit, 1891; aged 80; died, June 18, of coronary thrombosis.

Cassius M. Craig, Champaign, Ill.; Medical College of Ohio, Cincinnati, 1882; aged 81; died, June 25, of bronchopneumonia.

Thomas Sylvester Kirby, Cartier, Ont., Canada; University of Toronto Faculty of Medicine, 1910; aged 53; died, May 3.

Robert Edward Ellzey, Cotton Valley, La.; Memphis (Tenn.) Hospital Medical College, 1913; aged 56; died, June 12.

Archibald Le Roy Rice, Los Angeles; Denver College of Medicine, 1902; aged 65; died in May of cerebral embolus.

Archibald C. Byars, Oakland, Calif.; Tennessee Medical College, Knoxville, Tenn., 1902; aged 68; died, May 17.

Caleb P. Soper, Cedar Falls, Iowa; Dartmouth Medical School, Hanover, N. H., 1883; aged 76; died, May 21.

Philip E. Hannah, Harrodsburg, Ky.; Southern Medical College, Atlanta, Ga., 1886; aged 74; died, May 14.

William Bell Meredith, Pearsall, Texas; Medical College of Alabama, Mobile, 1874; aged 87; died in May.

Correspondence

DOCTORS ON COINS

To the Editor:—I am much interested in your comment on the article from the *Centaur of Alpha Kappa Kappa* (THE JOURNAL, August 6, p. 536) on the portraits of medical men on postage stamps. So far as I know the numismatists have not fared as well as the philatelists. I have an Austrian two shilling piece struck in 1929 bearing the profile of Theodor Billroth. I know of no other coin bearing the portrait of a physician and would be glad to hear from interested physicians if other such coins have been issued by any country.

EDGAR F. KISER, M.D., Indianapolis.

"CONCENTRATION OF CHLORIDE, SODIUM AND POTASSIUM IN URINE AND BLOOD"

To the Editor:—My attention is called to two errors in the bibliography of the paper entitled "Concentrations of Chloride, Sodium and Potassium in Urine and Blood: Their Diagnostic Significance in Adrenal Insufficiency" by Cutler, Power and myself in THE JOURNAL, July 9. The reference to Gordon, Sevringhaus and Stark should be Gordon, E. S.; Kimble M. S., and Sevringhaus, E. L.: Potassium Tolerance Tests in the Study of Asthenias, p. 31, Program of Central Society for Clinical Research, Chicago, November 1937. The reference to Zwemer and Truszkowski should be *Proc. Soc. Exper. Biol. & Med.* 35:424-426 (Dec.) 1936.

RUSSELL M. WILDER, M.D., Rochester, Minn.

AIR CONDITIONING AND INDUSTRIAL HEALTH

To the Editor:—In the June 25 issue of THE JOURNAL, page 2142, Dr. Leverett D. Bristol has reported his observations under the heading of "Air Conditioning and Industrial Health." From his experience he states that "there is no evidence to indicate any improvement in incidence or duration of sickness among a group of about 1,000 people working in scientifically controlled air conditioned space as compared with a control group of approximately the same size working in non-air conditioned quarters ventilated by the usual mechanical and natural methods."

In commenting on these findings he says: "The somewhat negative results in this comparative study may be based not so much on the lack of influence of air conditioning on absence because of sickness as on the satisfactory quality of the ventilation in this particular instance available to the control, non-air conditioned group."

This is a pertinent observation, but I believe that he has overlooked another factor, and that is the fact that the workers at most were in the air conditioned environment from seven to eight hours a day probably five days out of the week. The remainder of their time undoubtedly was spent in surroundings much less desirable or healthful. For this reason I do not see how one could expect that their exposure to an air conditioned environment for forty hours a week would result in a general improvement of their health. If these people went home to an air conditioned house or apartment, one could then expect that they would be in an air conditioned environment about two thirds of the time and should show some improvement in their general health; but unfortunately one is not able to make such comparisons at this time.

I mention this because a similar report has been made by the Metropolitan Life Insurance Company, comparing the incidence of illness between their employees in their air conditioned building with those in a non-air conditioned building. These reports

are undoubtedly of value, but they should not be used as an argument against the healthful effects of air conditioning properly used. I believe that it would be important to have an industrial survey report showing the incidence of accidents in a factory before and after air conditioning. In other words, I believe that the workmen are placed at a real advantage when they are subjected to an air conditioned environment, but this cannot be expected to carry them through the remaining sixteen hours of the day any more than one could expect a dose of insulin given in the morning to take care of the carbohydrates that a diabetic patient eats for his evening meal.

ALBERT G. YOUNG, M.D., Brookline, Mass.

Medical Director, Corey Hill Hospital.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

RECURRENT SMALLPOX AND SMALLPOX AFTER VACCINATION

To the Editor:—Is it possible for a person who has been vaccinated and whose vaccination has taken to have smallpox one year later? Also is it possible for one who has had smallpox once to have it again? In a controversy that is waging, I maintain that neither is possible, but I should like authority to support me.

H. R. RASOR, M.D., Mancos, Colo.

ANSWER.—In this answer the statements in the question are taken at their face value. In the absence of all details with regard to the kind of vaccine used, the nature of the take and the symptoms of the attack of smallpox, only general answers to the questions can be given.

Immunity is always relative. Vaccination with typical take practically always protects against smallpox much longer than one year, but at the beginning of the second year after vaccination a gradual loss of immunity begins. It is possible that in very exceptional cases smallpox may develop in a person vaccinated with a take a year previously. Cases of that kind have been observed. Even smallpox itself does not always protect against smallpox. Two or even three attacks of smallpox may occur in the same person. In fact, varioloid is the name of a modified form of smallpox in a patient who has had a previous attack or has been vaccinated. Jenner mentioned an instance of five attacks of smallpox in the same person.

CHOCOLATE CYSTS OF OVARIES

To the Editor:—A patient aged 24 has had a bilateral oophorectomy for bilateral chocolate cysts of the ovaries. No implantations were noted at the time of the operation. The cysts had not ruptured and there were only moderate adhesions in the culdesac. How soon would any implantations disappear postoperatively if ovarian extract is not given? When is the proper time to start glandular therapy? What type of endocrine therapy and how much should be used in such a case? M.D., Illinois.

ANSWER.—Chocolate cysts of the ovaries were a gynecologic mystery until the epochal work of Dr. John A. Sampson, reported by him before the American Gynecological Society in May 1921. He stated the belief that the endometrial tissue is implanted in the ovary as a result of back flow of menstrual fluid, with its particles of desquamated uterine mucosa, through the tubal ostia. This endometrial debris enters the ovary through the ruptured follicle. (This idea discards the older theory of embryonic inclusion of müllerian epithelium in the ovaries.)

Another theory for the presence of this endometrial tissue in the ovaries is through the venous circulation, which would constitute a metastasis. Against this theory is the fact that metastasis of endometriomas from pelvic implants of similar tissue do not occur.

This implanted endometrial tissue under the influence of estrogenic stimulation is subject to the cyclic changes characteristic for normally placed endometrium in the uterus, with resultant accumulation of endometrial debris, hemorrhage and cyst formation containing dark, tarry, chocolate appearing material. These cysts may rupture into the pelvic cavity with

resultant implants, forming dense adhesions containing endometrial adenomas. The belief is current that implants from chocolate cysts are more invasive than those of uterine origin but are not malignant.

In the patient in question the cysts had not ruptured, but there were moderate adhesions in the culdesac indicating that these were implants from an undiscovered ruptured cyst or from menstrual debris escaping from the tubes.

With removal of the ovaries, these endometrial implants should atrophy in the same manner in which the uterine endometrium will atrophy following castration. This is the result of removal of estrogenic and luteal stimulation, inherent to the ovary. That these endometrial implants will atrophy beyond the stage of quiescence is doubtful. It is reasonable to believe that estrogenic treatment will reactivate the atrophied implants that remain.

Werner and his associates have shown that, in castrate girls, 5,000 international units (approximately 1,000 rat units) of theelin in oil given as a total dosage over a period of one month will stimulate endometrial growth, with resultant bleeding following its discontinuance (Werner, A. A.; Jones, Grey; Roberts, John; Broun, G. O.; Neilson, C. H., and Rothermich, N. O.: Effective Clinical Dosages of Theelin in Oil, *THE JOURNAL*, Sept. 25, 1937, p. 1027).

If one is not sure that the pelvic cavity is entirely clear of these implants, it is questionable whether the patient should have estrogenic therapy. Should the patient suffer considerably from menopausal symptoms the only other treatment that could be suggested would be to give the patient sedatives, such as chloral hydrate 0.16 Gm. (2½ grains) three times a day or elixir of phenobarbital 4 cc. (1 drachm) three or four times a day or any other desirable sedative. This of course should be discontinued as soon as possible.

It is well to determine the activity of the patient's thyroid; if its activity is low, desiccated thyroid may be added to the treatment.

ALLERGIC RHINITIS IN FARM BOY

To the Editor:—A boy aged 2½ years has had rhinitis since he was 9 months old. He is the only child of healthy parents. His mother and a maternal uncle have hay fever. There is no history of allergy on the father's side. The child seemed to have colic on a diluted whole milk formula, but he did nicely when the formula was changed to evaporated milk. He had a mild facial eczema when 3 months old. All the usual foods were added to his diet gradually without any evidence of allergy being manifest. His nutritional status has been good until this winter, when almost constant rhinitis resulted in a decreased appetite. The rhinitis becomes definitely worse following exposure to horses or chickens. He has had several asthmatic attacks, which were preceded by intimate contact with horses or articles which had been in contact with horses. Scratch tests are positive to milk, chicken feathers, duck feathers, goose feathers, dog hair, cat hair and horse dander, and also to kapok. Digital examination reveals an adenoid which is not significantly enlarged. The nasal mucosa is pale and boggy. The family lives on a farm within 50 yards of the barns. The house is of modern construction and it is heated by a hot air furnace which draws the air to be heated from return vents in the floors of the rooms. The child's room has been made as dust proof as possible. He uses no pillow and his mattress has been encased in a rubberized cloth, even though it is of a good quality felt construction. His toys have been carefully selected to avoid allergens. There is an incubator in the cellar. It has been noted that the rhinitis is worse following a hatch of chicks. The living-room furniture has down cushions. Soon after entering the living-room he had attacks of sneezing. He has been barred from the cellar and the living-room. Will you kindly advise me as to the treatment I can pursue to make him more comfortable? The parents are able to have the boy removed from the farm for one month, but for economic reasons they cannot afford a longer period. Should I undertake desensitization during that month? What allergens should I use and what procedure should I follow?

NELSON NEWMARK, M.D., Springfield, Mass.

ANSWER:—It is assumed from the excellent history given that the child has been examined for sensitivity to all the other foods he eats (eggs, wheat, corn, oats, meats, vegetables, fruits) and to the other common inhalants (wool, goat hair, cow hair, cottonseed) with negative results. Frequently, in the presence of perennial rather than seasonal symptoms, one may overlook the importance of pollens as a cause of trouble. This may be important especially for those living on a farm where pollens (especially those of the grasses) are found all the year round in barns. It is assumed, however, that these causes have been considered and ruled out by the examiner. We then have a patient 2½ years old, sensitive to milk, horses, feathers and cat and dog dander, living in a most unfavorable environment, a farm house only 50 yards away from the barns. The question of milk sensitivity has been well handled by giving heated (denatured) milk. It should be noted that cream should be avoided in these patients because of its content of lactoglobulin and lactalbumin in an undenatured state. The best treatment for the inhalant sensitivity is the removal of the patient from these inhalants. This pro-

cedure is so superior to attempts at "immunization" that the question of economic difficulties should be thoroughly and carefully investigated in the light of the importance of such a step for the child's health before it is considered impossible. Such a step is much more important in infancy before the development of chronic asthma with its complications than several years hence when, in spite of economic difficulties, it may have to be taken. The removal of the child even for one year from the farm to an environment free from feathers, horse dander and the other substances, aided possibly by careful and judicious hyposensitization, is to be strongly recommended.

If such a procedure is found impossible, one should clean the house of as much of the offending environmental substances as is possible. The incubators must be moved from the house, and the basement thoroughly washed of all accumulated dust which may contain particles of feathers. No matter how careful one may be, it is hardly possible to avoid the presence of fine, microscopic feather dust in a house containing an incubator in the basement. All down furniture should be removed from the house as soon as practicable. The furniture should be either reupholstered with horsehair or moss (sterilized horsehair as prepared for upholstery is not allergenic even to horse sensitive cases) or should be replaced by simple unupholstered furniture (cane or imitation leather covered chairs).

The other inhalant and contact substances mentioned may be more readily removed from the house. Dogs and cats should be strictly interdicted. The rugs and furniture that may contain their danders should be thoroughly cleaned. The avoidance of horse dander is not easy in the situation described. Riding clothes, work clothes used in the barns, manure spread as fertilizer for a garden immediately adjacent to the house—all these and many more factors that will suggest themselves to the doctor on the scene are of vital importance and must be eliminated from the patient's environment. No one should be permitted to enter the house without at least changing his work clothes if he has been in contact with chickens or horses.

In spite of all these precautions, the wind blowing from the direction of the barns or from the chicken houses may bring enough material to cause trouble. The child's room should, if possible, be moved to a part of the house most protected from this influence. Hyposensitization may be started with feathers while he is away from home for the month mentioned. The dose depends on the reaction of the patient. One cannot start with too low a dilution for the sake of safety. One-tenth cc. of a 1:1,000,000 solution of a commercial preparation given subcutaneously is probably a safe starting dose. The dosage should be raised individually in each case. The interval may be once in three days to once a week. No injection should be given until all induration is gone from the previous dose. As the dose is increased to the maximum tolerance, the interval is lengthened to about once in two weeks and the treatment maintained for as long as needed.

It would not be wise or safe to attempt hyposensitization with both feathers and horse dander simultaneously. If possible, one should avoid the injection of horse dander because of the danger of serious reactions. If it is used, it should be started even more cautiously than feathers. Finally, one must keep in mind that such patients are usually highly sensitive to horse serum and that the administration of any antitoxin made from horse serum is dangerous.

MASSIVE HYPERTROPHY OF BREASTS

To the Editor:—A woman aged 26, unmarried, has enormous hypertrophy of both breasts, which began shortly after puberty and has continued to the present. Are there any data as to the progressiveness of such a condition? It has a bad effect on the patient's psyche, as it seems to be a detriment to a possible marriage. What is the latest treatment by means of plastic surgery? CLARENCE A. WELLS, M.D., Quincy, Ill.

ANSWER:—Massive puberty hypertrophy of the breasts is an uncommon condition and, as the name implies, it usually begins to manifest itself at puberty, shortly before or after the menarche. Both breasts are usually involved but one may be considerably larger than the other. Generally the breasts grow excessively for a few months, reaching the maximum within two years. This patient has the rarer type, in which the condition continues to progress until radical treatment is instituted. The exact cause is unknown but one or more endocrine glands are involved in the process. Geschickter, Lewis and Hartman believe that the histology of gynecomastia, puberty development and puberty hypertrophy of the breast is the same. They produced typical gynecomastia in the monkey by injections of estrogenic substance. This as well as other

evidence seems to indicate that puberty hypertrophy of the breasts is an exaggeration of the normal growth changes which occur at puberty and that the direct stimulus for the breast enlargement is derived from estrin and possibly also from progesterin.

At the present time there is no satisfactory way of treating puberty hypertrophy except by surgical measures. Operations for this condition can be performed whereby the patient can be assured a reduction in size of the breasts with normal configuration and location, proper position of the nipples and areolas in the new breasts, ample blood supply and little if any disturbance in breast function. Excellent descriptions of satisfactory operations have been given by Samuel Fomon (*Arch. Surg.* 33:253 [Aug.] 1936) and by Jacques W. Maliniak (*ibid.* 31:587 [Oct.] 1935).

SPASTIC PARAPLEGIA

To the Editor:—A man, aged 34, was diagnosed as having neurosyphilis at least eight years ago. He had a left hemiplegia in 1931, which cleared up after three or four months, and a year later he had a syndrome of spastic paraplegia, the arms not being involved. The blood and spinal Wassermann reactions at that time were both positive and a syphilitic gold curve was present. He was given malaria and about a year of continuous chemotherapy between 1932 and 1934. Since then he has had mercury rubs and potassium iodide. His blood Wassermann reaction is positive but the spinal Wassermann reaction is negative. The patient has daily massaged his limbs so that in spite of the fact that he is continuously in a wheel chair the disuse atrophy is surprisingly small. The knee jerks are hyperactive bilaterally, and a positive Babinski is present bilaterally. The spasticity is not painful. The cranial nerves are intact; there are no sensory or bladder disturbances. His general physical condition is good. Do you think that the Foerster operation for spasticity would be worth trying in such a case? He is anxious to try anything that may possibly help.

M.D., California.

ANSWER:—The opinions of syphilologist, neurologist and neurosurgeon would indicate that this patient is not a likely candidate for the Foerster operation. It might be that an examination would change that opinion but, in view of the fact that the spasticity is not painful, the advisability of such an operation is questionable. Of course, before expressing a concrete opinion with regard to such an operation it would seem advisable to become more familiar with the condition of the patient's spinal cord to determine whether or not there is degeneration or compression of the spinal cord present. While it is true that the operation might relieve some of the spasticity, it is questionable that it would in any way increase the patient's ability to walk, and in view of the fact that there is no pain, such an operation does not seem warranted.

TOXICITY OF PHENOL IN PRESCRIPTION

To the Editor:—Could the following prescription possibly be harmful to a patient:

℞ Phenol	1 minim
Glycerin	10 minims
Peppermint water.....	sufficient to make 1 ounce

Take contents of bottle without water.

What would be the lethal dose, idiosyncrasy and toxicity of such a mixture?

M.D., North Carolina.

ANSWER:—This prescription contains only two ingredients that might have a decided systemic action, phenol and peppermint, the water and glycerin being merely the vehicle.

Peppermint water contains about 0.2 per cent of oil of peppermint. The prescription contains 0.06 cc. (1 minim) of the oil. The U. S. P. dose of the oil is 0.1 cc. (1½ minims). Although no data are available as to the exact toxicity of oil of peppermint, a case is known in which about 1 ounce of the oil was taken through carelessness, the only noticeable results being a laxative action and a burning at the anus.

Phenol has a U. S. P. dose of 0.06 Gm. (1 grain), and for the liquefied phenol (90 per cent phenol and 10 per cent water) 0.06 cc. (1 minim). Glycerin favors the absorption but decreases the potency of phenol, but the small quantity of glycerin present in this prescription would have practically no such influence.

The toxicity of phenol varies widely for different individuals. Children are more susceptible than adults. In the adult wide variations have been reported by investigators; 5 Gm. (75 grains) has been reported as causing death. Other investigators have reported the fatal dose as varying between 8.5 and 60 Gm. Thus the minimum lethal dose for man cannot be fixed accurately. In young children poisoning has been reported from 0.2 to 0.5 Gm. (3 to 8 grains) when given in 3 per cent solution. Absorption and elimination are rapid, so that a cumulative action rarely results. Since phenol is largely detoxified in the liver

there is much less systemic action if absorbed from the stomach than if absorbed from the skin of the bladder.

From these facts it would appear that many times the quantity of this prescription, in which the dilution of the phenol is less than 0.2 per cent, would be required to cause any serious disturbance, and the lethal dose of the prescription would be extremely large.

INJECTIONS FOR ECHINOCOCCUS CYST

To the Editor:—Two months ago I operated on a patient for an echinococcus cyst. The cyst was too large to enucleate entirely, so I cleaned it out as much as possible and put a rubber tube into the cyst cavity. Can you suggest some nonoperative method by which I could obliterate the cyst cavity and thus permit it to close? I was thinking of the possibility of injecting some substance into the cavity for this purpose.

M.D., New Jersey.

ANSWER:—Prolonged drainage from an incised echinococcus cyst frequently occurs and is due to persistence of daughter cysts, failure to destroy the chitinous lining and secondary infection. For this reason it is preferable, after a satisfactory exposure and isolation, to aspirate the cyst, inject it with 2 per cent liquor formaldehydi, then incise and remove the chitinous membrane, close up the cavity and obliterate the dead space. Mopping out the cavity or injecting it with from 2 to 4 per cent liquor formaldehydi after the cavity has been draining for several weeks is not as effective but may still bring results. If the cyst referred to is in the liver, special care should be exerted not to break up the adhesions around the sinus and spill the formaldehydi solution into the free peritoneal cavity. The injections should not be repeated too often, as they may result in a prolonged drainage of the bile.

ULTRAVIOLET LAMP FOR CORNS

To the Editor:—I have an ordinary Sun-Rival Ultraviolet lamp using a number 68 Everready carbon. By employing a number 20 plus spherical lens to concentrate the rays from this lamp, can corns and warts be removed? Is bichloracetic acid better than concentrated light in the treatment of corns?

ROBERT MONFORT, M.D., Onaway, Mich.

ANSWER:—Concentration of light rays on callosities cannot be expected to be of much value in their removal. The penetration of light rays is so slight that even strongly concentrated radiation is not particularly effective for this purpose. The use of concentrated acids for removal of corns or callosities is likewise not recommended because of danger of damage to normal tissues.

The most logical treatment is to pare down the callosities under antiseptic precautions as much as possible by means of a sharp scalpel, going only to the depth of the normal tissues. Following such paring, occasionally an application of an ointment containing 30 per cent salicylic acid in hydrous wool fat may be used to soften the deeper portions of the callosity, after which further cautious paring may be done. The important point in the treatment of corns is to remove friction. For this purpose the callosity should be shielded until it finally disappears, and carefully fitted shoes should replace the ones which have produced the corns. Even if corns are removed, they will promptly return unless the friction that caused them is eliminated.

DANGERS FROM GALVANIZING SHEET METAL

To the Editor:—Is exposure to the fumes of acids arising from the vats in the process of galvanizing sheet metal recognized as a direct or contributing factor in the development of pulmonary disease? Reference to authoritative literature would be appreciated.

M.D., Wisconsin.

ANSWER:—In general galvanizing work the chief fume produced is zinc oxide, which is not an acid. This fume may give rise to metal fume fever, which is primarily a respiratory disease (Sayers, R. R.: *Metal Fume Fever and Its Prevention*, *Pub. Health Rep.* 53:1080 [July 1] 1938). Extensive work also has been reported by Drinker and his associates (*J. Indust. Hyg.* 9:88, 98 [March], 187 [May], 331 [Aug.] 1927). Ammonium chloride is widely used as an overlying coating above molten metal, which might lead to respiratory irritation but has attracted little attention. In the galvanizing of metal sheets, some plants make use of a bath of molten or flaming sulfur, which may become sulfurous acid. This gas or vapor is highly irritating in low concentrations. The effects of sulfur dioxide have been discussed by Kehoe and others (but with reference to another industry) in an article in the *Journal of Industrial Hygiene* (14:159 [May] 1932) entitled "On the Effects of Prolonged Exposure to Sulfur Dioxide."

However, in the preparation of sheet metal prior to galvanizing, sulfuric acid vapors may appear and may be irritating.

Ordinarily, sulfuric acid will not evaporate. Acid may leave pickling vats as a constituent of steam and on the evaporation of the water component may be present in high concentrations. Such acid vapors may induce inflammation of the upper respiratory with bronchitis. In any given galvanizing room, if the galvanizing pots producing zinc oxide are near pickling vats, which may emit sulfuric acid, their combination may take place in the atmosphere, leading to zinc sulfate, which is a definite irritant. This combination has led to inflammation of the gastrointestinal tract eventuating in ulceration (McCord, C. P.; Friedlander, Alfred; Brown, W. E., and Minster, Dorothy K.: An Occupational Disease Among Zinc Workers, *Arch. Int. Med.* 37:641 [May] 1926).

This industrial operation, under certain conditions, may provoke several occupational diseases, but involvement of the respiratory tract does not stand out as preeminent.

MIXED VACCINE IN BRONCHITIS

To the Editor:—A man aged 58, a pilot, complains of chronic bronchitis of many years' duration. He has had various treatments by a number of physicians with little or no relief. On two occasions during the last year, the treatment consisted of Lederle's combined pertussis vaccine. The patient reports that there is more relief from this treatment than from anything else he has received. Is the result psychic or is the treatment of benefit?

GEORGE GOOD, M.D., Union City, N. J.

GEORGE GOOD, M.D., Union City, N. J.

ANSWER.—Various types of vaccines have been used in the treatment of chronic bronchitis and chronic bronchial asthma. The preparation given is representative of most of the respiratory vaccines used except that it also contains Bardet bacilli. No one has proved any special virtue in the use of the latter organisms in chronic bronchitis or asthma, nor is there any definite proof that autogenous are better than stock vaccines.

The apparently good results obtained were probably not psychic but similar to those obtained by the administration of other nonspecific proteins, which unfortunately are usually of only temporary duration. To obtain success with vaccines many believe that it is necessary to inject doses large enough to obtain definite local reactions. If asthma also is present the patient should be given the benefit of thorough cutaneous testing. Something in the environment or diet may be discovered the removal of which may be of great service to the patient.

BLADDER AND RECTAL COMPLICATIONS FROM SUBARACHNOID ALCOHOL INJECTIONS

To the Editor:—Is it possible to have bladder complications (retention or incontinence) without rectal complications (incontinence) following the subarachnoid injection of absolute alcohol? What is the incidence of bladder dysfunction following the subarachnoid injection of absolute alcohol, and what is the average duration and prognosis?

M.D., Florida.

ANSWER.—It is impossible to give accurate data concerning the incidence of loss of vesical function or the incidence of rectal incontinence following subarachnoid injections of alcohol. It is possible to have vesical complications such as retention or incontinence without rectal complications, or vice versa, following the subarachnoid injection of absolute alcohol. It is not possible to predict, prior to such an injection, whether a patient will lose control of the bladder or rectum, or both, but a patient on whom this procedure is to be performed should be impressed with the fact that either or both of these complications may occur. Likewise, it is not possible to give any accurate data as to how long these complications will persist if they do occur and, consequently, the prognosis necessarily must be guarded in each case.

DANGERS OF INTRAVENOUS INJECTION OF DEXTROSE SOLUTION

To the Editor:—Are there any reported harmful effects resulting from the continued use of dextrose intravenously? M.D., West Virginia.

ANSWER.—Experimentally in animals 10 per cent dextrose in water given intravenously has produced serious and even fatal results from amounts comparable to those used clinically. There is such a variation in the indications and course of the conditions for which dextrose solutions are given that it is difficult to outline more than their general use, particularly since there are so many diverse opinions.

The maintenance of the water balance is of importance particularly when given over a period of time, unless it is the intent as in cerebral edema to dehydrate the patient. It is only when chlorides are indicated that they may be added to a weaker solution, such as one of 2.5 per cent. Rarely is it indicated in ordinary conditions such as after operation to give more than

a 5 or 6 per cent solution. The urine should be tested frequently for sugar. A practical method of checking the water balance is by determining the twenty-four hour output and specific gravity of the urine. Blood chemistry estimations are more accurate but frequently too expensive to be practical. Locally, thrombophlebitis occurs more frequently after the high concentrations.

One must try to avoid the *extreme discomfort, tendency to pressure sores and pulmonary edema* resulting from the patient's lying in one position for continuous or prolonged intravenous administration.

GRINDING TEETH IN CHILD

To the Editor:—A little girl, aged 4½, who seems in splendid health, has acquired the habit of crunching or gritting her teeth while asleep, especially when she lies on her back. I have consulted various books but find no mention of this condition. Could you please tell me the cause of such a condition and treatment?

M.D., Louisiana.

ANSWER.—The exact cause for grinding or gritting of the teeth has not yet been determined. The condition, however, seems to occur most frequently in children of so-called neuro-pathic constitution. These children, as a rule, are restless and irritable, and they sleep more or less poorly. The condition in itself does not result in any damage to the teeth in the majority of instances, nor does it seem to have any detrimental effect on the health. With increasing age the disorder, in almost every instance, disappears. Treatment should be directed toward the reduction of the child's nervousness, by assuring an opportunity to obtain plenty of rest, sleep, fresh air and sunshine. Calcium therapy given concurrently with vitamin D preparations is suggested in some cases.

ALOPECIA AREATA

To the Editor.—A man aged 30 has been gradually losing his hair in three large spots on his head. It pulls out without any sign of a root but leaves the scalp smooth. It doesn't change in color. Please advise as to treatment.

M.D., Idaho.

ANSWER.—The patient has alopecia areata. This may be due to nervous shock or to long continued mental strain. Attention should be paid to the patient's general physical condition and any foci of infection removed. Locally the affected areas can be painted lightly by the physician every ten days with a 50 per cent solution of trichresol. Every other night the areas can be anointed with a 12 per cent sulfur ointment or, if preferred, the following lotion can be rubbed in:

Mercury bichloride	0.02
Chloral hydrate	8.
Spirit of formic acid	15.
Castor oil	1.
Alcohol	sufficient to make 180.

The quartz lamp is also of value in certain cases. Sufficient treatments should be given to cause an erythema and they should be given once or twice weekly.

TERPIN HYDRATE IN ISO-ALCOHOLIC ELIXIR

To the Editor:—IN THE JOURNAL, Sept. 14, 1935, Bernard Fantus presented in an article on advances in therapeutic technic an example of the use of an iso-alcoholic elixir consisting of *terpin hydrate* 5 Gm. and iso-alcoholic elixir to make 60 cc. I have been unable to have the prescription filled. One druggist asked the patient to return in twenty-four hours; others refused to attempt it. One druggist filled it but the mixture was cloudy. Why? ROBERT M. HOLLAND, M.D., Boston.

ROBERT M. HOLLAND, M.D., Boston.

ANSWER.—There is no incompatibility whatever when the high-alcoholic elixir (N. F. VI) is employed, as is obviously intended when iso-alcoholic elixir is prescribed: terpin hydrate requires a highly alcoholic vehicle for solution.

ALLERGIC BLEPHARITIS

ALLERGIC BLEPHARITIS

To the Editor:—In Queries and Minor Notes in THE JOURNAL of July 16 Dr. E. H. Brown's question on allergic blepharitis suggests that my own case might be of interest. For some years I have been subject to occasional attacks of blepharitis, which I believe are allergic in nature because of the conditions of their onset, the accompanying symptoms and the response to treatment. The attacks most often occur after driving in the country or exposure to the dust of pillows. They are usually preceded by a short, dry cough and tickling in the chest and throat, so slight and of such short duration that I only recently connected it with the blepharitis; severe attacks are often accompanied by nasal congestion and the misery of hay fever. A 1 per cent solution of ephedrine sulfate sprayed into the nose when an attack threatens has for three months now been completely effective in forestalling the attacks; if the swelling has already begun, a little of the same solution directly in the eyes causes rapid remission of the symptoms. EDWARD R. SMITH, Meriden, Conn.

EDWARD R. SMITH, Meriden, Conn.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, August 20, page 743.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Examinations will be held in all centers where there is a Class A medical school and five or more candidates who wish to write the examination, Sept. 12-14. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An affiliate of the American Board of Surgery. New York, Oct. 21-22. Applications must be filed sixty days prior to examination. Sec., Dr. Paul M. Wood, 745 Fifth Avenue, New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILIGOLOGY: *Written.* Various large cities in the country about Oct. 1. *Oral.* St. Louis, Nov. 11-12. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written* examinations will be held in various parts of the United States, Oct. 17 and Feb. 20. Application for the October examination must be received before Sept. 15 and for the February examination on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written* examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada, Nov. 5. Last date for applications is Sept. 5. General examination for all candidates (Groups A and B) will be given in St. Louis, June. Applications must be filed not later than sixty days prior to date of examination. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: New York, Oct. 7, and Washington, D. C., Oct. 8. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Memphis, Tenn., January. Applications for this examination must be filed with the Secretary on or before Oct. 15. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Washington, D. C., Oct. 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: Detroit, October 26; Rochester, N. Y., November 13; and Oklahoma City, November 15. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 28-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlantic City, N. J., Sept. 15-18. Sec., Dr. Byrl R. Kirklin, 102-110 Second Ave. S.W., Rochester, Minn.

AMERICAN BOARD OF UROLOGY: New York, Jan. 13-15. Applications must be submitted not later than Oct. 1. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

Kansas June Examination

Dr. J. F. Hassig, secretary, Kansas Board of Medical Registration and Examination, reports the written examination held at Kansas City, June 7-8, 1938. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Eighty-three candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1938)		80.5
Northwestern University Medical School.....	(1938)		87.9
Rush Medical College.....	(1937)		85.5
University of Illinois College of Medicine.....	(1938)		85.5
University of Kansas School of Medicine.....	(1938)		79.
80.6, 81, 81.6, 81.7, 82, 82, 82.2, 82.3, 82.5, 82.7, 82.9, 83, 83, 83.2, 83.3, 83.4, 83.5, 83.5, 83.6, 83.7, 83.9, 84, 84.2, 84.2, 84.4, 84.7, 84.8, 84.8, 84.9, 85, 85, 85, 85.2, 85.5, 85.5, 85.7, 85.8, 86.1, 86.7, 86.3, 86.4, 86.5, 86.5, 86.6, 86.6, 86.9, 86.9, 86.9, 87.3, 87.4, 87.6, 87.7, 87.7, 87.8, 88.3, 88.4, 89, 89, 89, 89.4, 89.8, 90, 90.2			
Boston University School of Medicine.....	(1930)		85.1
Creighton University School of Medicine.....	(1937)		81.9,
(1938) 77.6, 80.4, 81.4, 82.3, 85.9			
University of Oklahoma School of Medicine.....	(1936)		82.2
Meharry Medical College.....	(1938)		83.2
University of Wisconsin Medical School.....	(1937)		84.7, 86.4
Medizinische Fakultät der Universität Wien.....	(1936)		80.5*

Thirteen physicians were licensed by reciprocity and two physicians were licensed by endorsement on May 10 and July 1. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Northwestern University Medical School.....	(1935)		Illinois
University of Illinois College of Medicine.....			Illinois
University of Kansas School of Medicine.....			Missouri
St. Louis Univ. School of Medicine.....			Missouri

Harvard University Medical School.....	(1932)		N. B. M. Ex.
* License has not been issued.			

Colorado June Report

Dr. Harvey W. Snyder, secretary, Colorado State Board of Medical Examiners, reports the written examination held at Denver, June 15-17, 1938. The examination covered 8 subjects and included 163 questions. An average of 75 per cent was required to pass. Forty-three candidates were examined, all of whom passed. Ten physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists.....	(1938)	78.5,	82, 83
University of Colorado School of Medicine.....	(1938)		80,
81, 81, 82, 82.5, 83, 83, 83.5, 84, 84, 84, 84, 84, 84.5, 85, 85, 85, 85, 85, 85, 85, 85, 86, 86, 86, 86, 86, 86, 87, 87, 87, 87, 88, 88, 89

*Licensed to practice medicine and surgery.			

Wyoming June Examination

Dr. G. M. Anderson, secretary, Wyoming State Board of Medical Examiners, reports the oral and written examination held at Cheyenne, June 2, 1938. The examination covered twelve subjects and included 120 questions. An average of 75 per cent was required to pass. Five candidates were examined, all of whom passed. Two physicians were licensed by reciprocity after an oral examination. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Colorado School of Medicine.....	(1937)		83
Northwestern University Medical School.....	(1938)		80*
Rush Medical College.....	(1937)		84
University of Illinois College of Medicine.....	(1937)		78
Creighton University School of Medicine.....	(1936)		77

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with

Univ. of Michigan Dep't of Medicine and Surgery.....	(1899)		Montana
* This applicant has received the M.B. degree and will receive the M.D. degree on completion of internship.			

South Carolina June Report

Dr. A. Earle Boozer, secretary, State Board of Medical Examiners of South Carolina, reports the written examination held at Columbia, June 27-29, 1938. The examination covered seventeen subjects and included fifty-six questions. An average of 75 per cent was required to pass. Forty candidates were examined, thirty-nine of whom passed and one failed. Eight physicians were licensed by reciprocity and one physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Emory University School of Medicine.....	(1938)		84
University of Pennsylvania School of Medicine.....	(1938)		86.9

Book Notices

General Technic of Medication: An Introduction to Medicinal Technology. By Bernard Fantus, M.S., M.D., Professor of Therapeutics, University of Illinois College of Medicine, Chicago. Third edition. Cloth. Price, \$2. Pp. 626. Chicago: American Medical Association, 1938.

The stated purpose of this book is to combat the slipshod methods so characteristic of many physicians in ordering medicines. While the author does not avowedly present a textbook on the prescription and is apparently far from considering his work a treatise on therapeutics, from the pedagogic point of view he nevertheless manages to make distinct contributions in both fields. It is indeed the reviewer's opinion that no finer book on prescription writing than this exists and that were its use compulsory in all medical schools the profession would rapidly advance in the "technic" of medication. But unfortunately few schools have a place in the curriculum for such "major" hours as a prescription course based on this work would require. Considering the book as a supplementary textbook in therapeutics only, one may question the advisability of burdening the student with pages of description of procedures which can be grasped in a few minutes of sharp watching in the hospital. Nevertheless there is something of undoubted value for the practicing physician on nearly every page of this book, and considering the essentially tedious nature of these subjects they are presented in a manner as little tiring as one could probably hope for. The third edition is brought well down to date and includes of course such alterations as were necessitated by new editions of the U. S. Pharmacopeia and the National Formulary.

The Psychology of Early Growth Including Norms of Infant Behavior and a Method of Genetic Analysis. By Arnold Gesell, Ph.D., M.D., Sc.D., Director of the Clinic of Child Development and Professor of Child Hygiene in Yale University, and Helen Thompson, Ph.D., Research Associate in Biometry, The Yale Clinic of Child Development. Assisted by Catherine Strunk Amatruda, M.D., Research Pediatricist, The Yale Clinic of Child Development. Cloth. Price, \$4. Pp. 290, with 30 illustrations. New York: Macmillan Company, 1938.

This latest volume from the clinic of child development at Yale University maintains the high scientific standards as well as the pleasing format of earlier publications. It takes the place of the volume, now out of print, on the Mental Growth of the Preschool Child and adds thereto a fully documented account of mental and physical growth during infancy on which have already been published *An Atlas of Infant Behavior, Infancy and Human Growth, and Infant Behavior*.

When a physician takes up a volume which describes stages of development, he expects, on the basis of physical measurements to which he is accustomed, to find quantitative determinations neatly and clearly defined which he may use with little or no qualifications as measures of progress. He may therefore feel somewhat at a loss at first in finding that no such simple and concrete measures are possible for determining behavior. He is apt not to realize that in dealing with psychomotor processes he is exploring a dynamic complex of which the outlines are indeed fundamentally regulated by intrinsic determiners but of which the expression is modified by a sensitivity to environmental influences.

The reviewer has recently had the opportunity to watch the efforts of a month-old monkey (*Macacus rhesus*) learning to use its locomotor mechanism. The animal could not yet sit up with any security. Nevertheless it was attempting to "muscle up" on parallel bars and to climb a trellis. Every now and then it would fall down on its back and could roll over prone only with help from its mother. Roentgenograms showed that its bodily development was already the equivalent of that of a child between 5 and 6 years of age. Therefore one may

assume, on the basis of Coghill's work, that the motor pattern in the monkey was already fully established and that learning and experience alone were necessary to transform its motor capacity into motor ability. It was engaging all postural and prehensile motor patterns at once. In two weeks' time the monkey had learned to use with fair efficiency its several motor capabilities.

Man however is born in a far more immature stage of development. The delimiting motor patterns complete themselves slowly. Prehensile capacity, though appearing early, undergoes progressive development over a period of eighteen months. Postural and locomotor capacity, though also appearing early, continue to develop so that the child is already 3 years old before he can learn to ride a tricycle.

This great extension of time for the development in man of motor patterns which are already complete in the monkey soon after birth means that infants must very gradually transform these slowly maturing motor capacities into motor abilities. There will then be unequal developments in motor patterns and seeming contradictions in motor abilities rendering impossible the definition of stages by simple rules. Each stage is represented by a constellation of activities, not by a single achievement. Once the physician has mastered this fundamental conception, he will have no difficulty in following the clearly described stages in development portrayed by the authors.

There are however five different fields of behavior for human psychomotor development, namely postural, prehensile, perceptual, adaptive and language. Although the constellation of achievement in each of these gives important information on the stage attained, the composite maturity levels of each must not be averaged. The maturity level in postural behavior, for example, is more accurately determined than that of social (adaptive) behavior because of the greater number of items in reference to posture.

There are allusions on page 223 to clinical relationships of stages attained in these several fields, but as the authors are concerned only with the achievements in health and in uninterrupted progress, these are merely sketched in outline. Nevertheless a careful study of the text, which is not to be accomplished without sweat and tears, will guide the clinician to a correct interpretation of his observations. The volume makes a distinct contribution to our study of the standards of health.

The Truth About Vivisection. By Sir Leonard Rogers, K.C.S.I., LL.D., M.D., Hon. Treasurer, Research Defence Society. Cloth. Price, 5s. Pp. 182, with 9 illustrations. London: J. & A. Churchill, Ltd., 1935.

Nowhere has there been a more complete or comprehensive puncturing of the claims of the antivivisectionists than in England, where two royal commissions have gone into the matter exhaustively and in each instance have brought in conclusions favorable to the continuation of the use of animals in research. They have, in other words, found the claims of the opponents of scientific research untenable. Yet, as this book points out, the activities of the antis continue unabated and are based, as always, on the same old tissue of lies, evasions, garbling of quotations, suppression of evidence, emotionalism, hair tearing, breast beating, and screaming charges which are never substantiated. This little book brings the picture of antivivisectionism in England down to date by cataloguing the activities of the sect since the second royal commission of 1905; the first royal commission met in 1875. The author points out that in spite of the findings of the royal commissions the antivivisectionists still:

1. Continue to deny and contradict the unanimous verdicts of two royal commissions.
2. Continue to deny the ethics of animal experimentation.
3. Continue to make their often refuted charges of cruelty.
4. Continue to use misleading statements condemned by the royal commissions.
5. Continue to waste donated and trust funds in the pursuit of objectives rejected by two royal commissions.

This book, which so completely, logically and devastatingly reduces all the claims of the antivivisectionists to absurdity and shows how their activities are contrary to the public interest, should be of great interest to American readers because American antivivisectionists adopt the same tactics and often fall back on quotations from British sources or cite conditions or experiences in England as a basis for their demands in this

country. A knowledge of the collapse of their movement in England under the pitiless and unimpeachable investigation of a royal commission in 1875 and another in 1906, plus the evidence that they have learned nothing and forgotten nothing as a result of these experiences, should lead to a renewed vigilance in this country against their possible inroads. They are constantly on the alert to break in. As this is written, they are endeavoring to initiate a measure in California under the specious title of "Humane Pound Law," which, if enacted, will cripple medical education in that state, to say nothing of placing handicaps on all research involving the use of animals and hampering the teaching of all the biologic sciences and the manufacture and testing of biologic products and many drugs.

The Practice of Urology. By Leon Herman, B.S., M.D., Professor of Urology, University of Pennsylvania Graduate School of Medicine, Philadelphia. Cloth. Price, \$10. Pp. 923, with 504 illustrations. Philadelphia & London: W. B. Saunders Company, 1938.

A new book on the practice of urology designed primarily for the general practitioner and surgeon should be of great aid to the medical profession in general. While not written in the usual textbook manner, the book should be of value to the medical student as a source of reference. Each section is well outlined and the work as a whole makes good reading. The sections dealing with the various aspects of the diagnosis and treatment of diseases of the urogenital system are discussed from the author's own point of view. It is of interest to note that he believes that nephropexy is again returning into favor among urologists. His discussion of the subject, however, is not convincing and the chapter ends with a plea for renal sympathectomy at the time of nephropexy in order to obtain best results. His discussion of the subject of lithiasis is not well balanced. Too much space is devoted to detailed description of dietary therapy of unproved value. The relative importance of excretory urography in diagnosis, particularly in the hands of the general practitioner, has not been sufficiently stressed. There is too little reference to European literature, and the quotations from American references are in some instances not as carefully selected as they might be. The illustrations are as fine as any to be found in present day volumes. Dr. Herman has given a valuable contribution to the field of medical literature and it is in keeping with the best traditions of Philadelphia medicine.

Public Health and Medical Licensure in the State of Mississippi 1789-1937. By Felix J. Underwood, M.D., Secretary and Executive Officer, Mississippi State Board of Health, and R. N. Whitfield, M.D., Assistant Secretary, Mississippi State Board of Health. Cloth. Price, \$1. Pp. 175, with illustrations. Jackson, 1938.

The Mississippi State Board of Health was formed in 1877, the necessary law having been modeled after that of Georgia, thus making the board of health essentially a product of the Mississippi State Medical Association. There was no appropriation until the following year, when the legislature granted \$250 for the salary of a secretary on a part time basis, \$1,000 for expenses of members attending meetings, and \$1,500 for books, stationery and supplies.

Mississippi had a severe epidemic of yellow fever in 1878. The town of Holly Springs had 1,440 cases with 304 deaths. The records of yellow fever at Orwood and Taylor kept by Dr. H. A. Gant were useful to Walter Reed in his experimental work on mosquito transmission. Dr. Gant, who was a member of the Mississippi State Board of Health from 1890 to 1901, was associated with Dr. H. M. Carter during this epidemic. When this book was written (1937) Dr. Gant was still living at Columbia, Tenn.; his recollections of yellow fever epidemics were recently published in the Mississippi Doctor.

The modern history period of public health in Mississippi began in 1910. Credit is given to Dr. W. S. Leathers for bringing the health work of the state from obscurity to prominence. The Bureau of Vital Statistics was established in 1912; the state was admitted to the death registration area in 1919 and to the birth registration area in 1921. A campaign against typhoid in one county in 1914 directed by a member of the U. S. Public Health Service was the beginning of federal participation in Mississippi's health program. Then came the beginning of full time county health departments about 1917,

and of malaria control in 1915. The Rockefeller Foundation gave financial assistance and personnel to organize the program and in 1929 a separate division of malaria control was established.

Joseph Goldberger and George Wheeler of the U. S. Public Health Service carried on experimental work on pellagra at the Mississippi Penitentiary, certain prisoners accepting the governor's offer of pardon for submitting themselves to the experiment. Goldberger and Wheeler concluded from the experiments that pellagra developed in at least some of the volunteers as a result of a restricted diet. The Mississippi State Tuberculosis Sanatorium was established in 1916. During the influenza pandemic in 1918-1919 there were 9,234 deaths reported in Mississippi and 213,104 cases. A Department of Child Hygiene and Public Health Nursing got under way in 1921 with Dr. Felix J. Underwood, then director of the Monroe County Health Department, in charge. A progressive public health law was approved by Governor Whitfield in 1924, in which year Dr. Underwood became state health officer. The book contains also discussions of public health regulations and biographies of those who have taken part in the development of public health work in Mississippi.

Feeding Behavior of Infants: A Pediatric Approach to the Mental Hygiene of Early Life. By Arnold Gesell, Ph.D., M.D., Sc.D., Professor of Child Hygiene and Director of the Yale Clinic of Child Development, the School of Medicine, Yale University, and Frances L. Ilg, M.D. Cloth. Price, \$4.50. Pp. 201, with 200 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1937.

This volume is devoted to the behavior aspects of infant feeding. It deals particularly with normal feeding behavior and minor deviations from it. The material in the first section of the book is based on a study of the general behavior development of normal children within the period from birth to six years. Then follow chapters covering the motor mechanisms of feeding, including suckling, mastication and swallowing. There is a description of the implements and technics of feeding, breast and bottle behavior, and behavior with spoon, cup, mouth and hands. The third section deals with the regulation of feeding behavior, while in the appendix there are included illustrative biographies. One of the most common problems facing the pediatrician are difficulties in the feeding of infants. The material in this book should aid him in meeting these problems. The descriptions of normal behavior will also guide the physician in directing the mother concerning the infant's training so that he may suggest attempts at training only when the infant is mentally and physically equipped to form the desired habits. This book will be found valuable not only to physicians but also to parents and students of child development.

A Handbook of Accepted Remedies: Symptoms and Treatment of Poisoning; Diagnostic Procedures; Miscellaneous Information. Edited by P. J. Hanzlik, M.D., Professor of Pharmacology, Stanford University School of Medicine, San Francisco, California. Department of Public Health, San Francisco, California, J. C. Gelger, Director. Second edition. Paper. Price, \$1. Pp. 115. San Francisco: J. W. Stacey, Inc., 1937.

The first edition of this book appeared in 1936. It contained data based in part on standard textbooks of pharmacology, therapeutics, toxicology and clinical pathology, Accepted Dental Remedies and various A. M. A. publications. The second edition, based on revisions of the same source books, includes such new items as Allantoin and Urea, Benzedrine, Crystalline Vitamin B, Mecholyl, Protamine Zinc Insulin, Sulfanilamide and Vinethene. Under "Poisonings," sections on Sulfanilamide and War Gases have been added. There is new material on calculation of doses for man which is not particularly significant. Also added are a nomogram for body surface, a description of the x-ray unit r, a table of the international atomic weights and some statistical formulas used in medicine. There is a new short section on official assays. Mercurochrome and Dinitrophenol have been omitted. It would seem advisable in subsequent editions for the author to refrain from including a title "Endocrine Disturbances" unless he extends the present list of endocrine principles to include their therapeutic uses. On the whole, the information contained in this book is very useful and it should save considerable time for those engaged in work which requires reference to these data. The author deserves much commendation for the excellent result of his efforts to include so much useful

data in a compact handbook. It may be presumed that it enjoys a popularity far beyond that of the staff of the San Francisco Hospital for which it was primarily designed.

Zur Entdeckung der Insulinschocktherapie bei akuten Geisteskrankheiten, insbesondere bei der Schizophrenie. Von Dr. Julius Schuster, gewesener I. Assistent der Pázmány Péter-Universität Psychiatrisch-Neurologischen Universitätsklinik in Budapest. Paper. Price, 2 pengő. Pp. 90. Budapest: Druckerel der Pester Lloyd-Gesellschaft, [n. d.].

This book is published by the author mainly to demonstrate his ability with this method. He tried to accumulate extensive material from the literature on insulin but unfortunately so carelessly that the excerpts lose the value which they had in the original papers. The clear understanding of hypoglycemic, pharmacologic shock in the interpretation of Sakel is to the author after many years of common knowledge apparently unknown. He has confused hypoglycemic shock with brain shock so called by him and in another place he does not differentiate both from allergic shock. The book is so confused that it cannot confuse anybody.

The Truth About Childbirth: Lay Light on Maternal Morbidity and Mortality. By Anthony M. Ludovici. Cloth. Price, \$2.50. Pp. 294. New York: E. P. Dutton & Co., Inc., 1938.

This amazing book stems its origin from the serious reveries of a serious layman. Mr. Ludovici, known to English and American readers as an experienced essayist, pondered on the hitherto inexplicable enigma that easy labor was the portion of primitive woman and dystocia the commonplace for her civilized descendants. From these reveries there arises a series of rational explanations supported by a broad, multilingual literature. Any doctor will be awed by this layman's erudition and thoroughness even though many of the conclusions may appear unwarranted. Each statement of fact is supported by the page reference of the author's authority. The chief defect of the book is that its author writes like a missionary. Throughout he is a humorless protagonist, a fire-eating zealot, a Don Quixote tilting at windmills. Moreover, through some distortion of vision he seems to think that physicians are in league with the devil and together they scheme, plot and strive to make labor annually more difficult and more unsafe.

In the introduction Mr. Ludovici disposes of the hoax that childbearing is an illness. He is convinced with full Freudian conviction that the current attitude to regard birth as an illness is the work of womankind, who subconsciously creates this lugubrious atmosphere as "a means of acquiring power over the male."

In chapter I Mr. Ludovici discusses easy childbirth, quoting extensively from explorers and anthropologists to prove that in yesteryear primitive women labored as rapidly and painlessly as do subprimate animals today. In chapter II he goes beyond this and argues that childbirth should actually be pleasurable. In the third chapter, which is, on normal childbirth, he points out that an average labor is not necessarily a normal labor, not more so than the average set of teeth in a community is necessarily a normal set of teeth. In the second part of this book, chapters IV to VIII, he considers the conditions of modern life which operate against normal, painless, pleasurable and safe childbirth.

All in all Mr. Ludovici has written a strong, thought-provoking book. It contains a wealth of intelligent material with an excellent bibliography and index. Many of the author's conclusions the reviewer takes issue with, as would most doctors.

Middle Age Is What You Make It. By Boris Sokoloff, M.D., Sc.D. Cloth. Price, \$1.75. Pp. 204. New York: Greystone Press, 1938.

This book on the hygiene of middle age was written by a physician who died in his early fifties. It is a difficult book to evaluate. In many respects it is far too technical for the lay reader, for whom it is intended. It is not sufficiently comprehensive for the physician. The author is obviously widely read in medical literature, but apparently he did not read with discrimination. He places too much emphasis on the change of the intestinal flora by the administration of lactose; he is, apparently, greatly impressed with the work of Metchnikoff on longevity, the result, perhaps, of an early association between the two men. His discussion of the interrelationship of the

glands of internal secretion is too complicated and too vague to do a lay reader any good, especially such advice as the closing note of one chapter in which he admonishes the reader to take good care of his gland of life, that is to say, his adrenal cortex. How the absorbed reader is to accomplish this feat does not appear. The book is extensively documented and most if not all of the references are to recognized authorities, but the conclusions and the applications of the work of these research workers is confused, inconclusive and inaccurate. While the book contains much good advice and a great deal of information which might be of considerable value, it is not a work which arouses enthusiasm.

Wissenschaftliche Forschungsberichte. Naturwissenschaftliche Reihe. Herausgegeben von Dr. Raphael Ed. Liesegang, Frankfurt a. M. Band XLVI: Virus und Viruserkrankungen bei Menschen, Tieren und Pflanzen: Biologische Einführung in die allgemeinen Forschungsergebnisse, praktischen Anwendungen und Arbeitsmethoden. Von Dr. med. Gustav Seiffert, Medizinalrat a. D., Planegg/München. Paper. Price, 16 marks. Pp. 221, with 7 illustrations. Dresden & Leipzig: Theodor Steinkopf, 1938.

In the first sixty-six pages of the book is a general discussion of the viruses, including among other things some of the recent work on the size of virus particles, chemical purification and immunologic considerations. The bulk of the book deals with virus diseases of man and animals. A small amount of space is given to diseases of plants and the virus-like forms such as the rickettsiae and bacteriophage. In concluding, a section is given on the methods used in the study of viruses. The book has definite value in acquainting the reader with some of the recent developments in this field, although it is too incomplete to serve as a reference guide to investigators.

The British Encyclopaedia of Medical Practice Including Medicine, Surgery, Obstetrics, Gynaecology and Other Special Subjects. Under the General Editorship of Sir Humphry Rolleston, Bt., G.C.V.O., M.D. Volume VII: Hyperchlorhydria to Leucorrhoea and Other Non-Haemorrhagic Vaginal Discharges. Cloth. Price, \$12. Pp. 759, with 171 illustrations. London & Toronto: Butterworth & Co. (Publishers), Ltd., 1938.

Volume VII is one of the largest of those included in this new encyclopedia. It goes from "hyperchlorhydria" to "leukorrhoea" and includes particularly important articles on such subjects as hypnotism, immunity, impotence, industrial accidents, infant feeding, insurance, diseases of the joints, labor, diseases of the larynx, and leprosy. Obviously, most important is the section on labor, which occupies more than 170 pages and thus constitutes a brief textbook of obstetrics. This book is as beautifully prepared and printed as are the other volumes of the series and presents adequately British points of view in relationship to the subjects discussed.

Social Service Department of the Mount Sinai Hospital of the City of New York: A Review 1927-1937. Paper. Pp. 80. New York, 1938.

"The first social worker in the Mount Sinai Hospital was appointed in 1906. In 1917 there was a staff of eighteen; in 1927 the staff consisted of forty persons; and in 1937 it has grown to a staff of fifty-four, including professional and clerical staff." The struggles during depression and the developments of social service work in the various hospital departments are explained in a popular manner. The whole constitutes a vivid picture of all the activities of one of the largest hospital social service departments in the country.

Diabetes Insipidus and the Neuro-Hormonal Control of Water Balance: A Contribution to the Structure and Function of the Hypothalamo-Hypophyseal System. By Charles Fisher, Ph.D., W. R. Ingram, Ph.D., and S. W. Ranson, Ph.D., M.D. Institute of Neurology, Northwestern University Medical School. Cloth. Price, \$5. Pp. 212, with 71 illustrations. Ann Arbor, Michigan: Edwards Brothers, Inc., 1938.

This volume is excellent in every respect with the exception of the title "Diabetes Insipidus" which appears on the binding. The use of this title would imply that the book contained information regarding the clinical syndrome of diabetes insipidus and its treatment. As a matter of fact, it contains nothing of a help to a practicing physician. It does, however, contain a complete review of knowledge regarding the pathogenesis of diabetes insipidus as determined by careful experimental investigations on animals. It is based on the superlative work performed in the Institute of Neurology, Northwestern University Medical School, and should be of interest to every experimental physiologist and to those students of disease who are interested in a fundamental approach to the problem.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Contracts: Salability of "Good Will" of Deceased Physician.—The defendant, on the death of her husband, a physician, sold to the plaintiff physician the practice and good will of her husband for \$5,000, a note being given for the purchase price. After making three monthly payments on the note the plaintiff was unable to make any further payments, having lost considerable of the practice which the deceased physician had had. The plaintiff made an unsuccessful effort to get the defendant to reduce the amount of the note and then instituted suit to cancel it and to recover judgment for the three payments already made. The trial court gave judgment for the plaintiff, and the defendant appealed to the St. Louis court of appeals, Missouri.

The question before the court was whether the business and good will of the deceased physician constituted a valid consideration for the note. In *Ryman v. Kennedy*, 141 Ga. 75, 80 S. E. 551, the Supreme Court of Georgia dealt with a similar question which involved the sale of a deceased lawyer's business for \$2,500 for which the purchaser had executed a promissory note. The maker of the note brought suit to cancel it and to recover all sums which had been paid on it, on the ground that the thing which the widow of the deceased lawyer attempted to sell was not a subject-matter of sale and that the note was therefore without consideration. The court, in ruling in favor of the maker of the note, used the following language:

Fees earned but not collected by the testator prior to his death, and all choses in action belonging to the testator in connection with his law business at the time of his death, and pending claims which the party of the first part had made arrangements with other attorneys to handle, were expressly excluded from the sale, and nothing was left upon which the contract could operate. The professional skill of the testator as a lawyer entered into the contract of employment by his clients, and the possibility that after his death his clients would consent to the selection of other counsel by the executors or others is too remote a contingency to render the "good will" of the testator a subject-matter of sale.

In *Re Caldwell's Estate*, 107 Misc. 316, 176 N. Y. S. 425, the court held as follows:

The business of a physician who specialized in x-ray pictures as an aid to physicians, and who had a high reputation in his specialized field, and had made many improvements and inventions in the art, had no "good will," transferable after death, and subject to transfer tax, since any good will was personal to the physician, and not to the place of business.

But after a man who has acquired a reputation for great skill or knowledge is dead, persons who would go to his office for the purpose of consulting him and availing themselves of his superior skill would not go there merely because the office was still open and occupied by another person, who had no reputation for superior knowledge or skill.

Again, in *Mandeville v. Harman*, 42 N. J. Eq. 185, 7 A. 37, the court, in discussing a question similar to that involved in the instant case, used the following language:

Professional skill, experience and reputation are things which cannot be bought or sold. They constitute part of the individuality of the particular person, and die with him. There can be no doubt, I think, that if the complainant was the most distinguished physician of the city of Newark, and had by far the most lucrative practice in that city, and he should be so unfortunate as to die next month or next year, it would be impossible for his personal representative to sell his good-will or practice, as a thing of property, distinct from the office which he had occupied prior to his death, for any price. . . . The practice of a physician is a thing so purely personal, depending so absolutely on the confidence reposed in his personal skill and ability, that when he ceases to exist it necessarily ceases also, and after his death can have neither an intrinsic nor a market value. And, if the complainant should make sale of his practice in his life-time, it is manifest all the purchaser could possibly get would be immunity from competition with him, and perhaps his implied approval that the purchaser was fit to be his successor; but it would be impossible for him to transfer his professional skill and ability to his successor, or to induce anybody to believe that he had.

Much stress was laid by counsel for the defendant on the advantage enjoyed by the plaintiff in obtaining the same office quarters which had been occupied by the defendant's husband. But, said the court, where the good will of a business is based

solely on the professional skill, personal ability, integrity, high standing, learning and acknowledged repute of the owner, then such good will is not dependent on any particular place or location. These qualities are not transmissible, and when the owner, who possesses these traits, dies, the qualities he possesses, the good will, is "gone with the wind." In giving such stress and prominence to the securing of the offices by the plaintiff which the defendant's husband occupied, the court opined that the defendant and her counsel overlooked the kernel of truth contained in certain lines, usually ascribed to Emerson, but which were tenaciously claimed by Elbert Hubbard, which ran as follows: "If a man write a better book, preach a better sermon, or make a better mouse-trap than his neighbor, though he build his house in the woods, the world will make a beaten path to his door."

The judgment of the trial court for the plaintiff was therefore affirmed.—*Magee v. Pope (Mo.)*, 112 S. W. (2d) 891.

Compensation of Physicians: Hospital Expenses Not Included in Physician's Fee.—The plaintiff, a physician, agreed with the defendant to undertake the antepartum care and the delivery of the defendant's wife for the sum of \$150. After the services were terminated the defendant refused to pay the fee, and the physician instituted suit. The trial court gave judgment for the plaintiff, and the defendant appealed to the court of appeal of Louisiana, Orleans.

The defendant admitted having made a contract with the plaintiff but contended that the sum agreed on was indefinite in that it was between \$125 and \$150 and that it was to include hospitalization. The issue between the parties, said the court, was narrowed to the sum of \$54 by the testimony and admission of counsel, since it was conceded that \$96 was due to the plaintiff, the cost of hospitalization being \$54. The probability, the court said, that the plaintiff included hospital expenses in naming a sum as the price of his professional services seems very remote. There was in the record the testimony of a physician, other than the plaintiff, to the effect that \$150 was a very reasonable fee for obstetric services in connection with the delivery of a child, particularly the first child. Both this physician and the plaintiff testified that greater skill and care are required and more difficulty is to be expected in the case of a primipara, especially when the mother has reached the age of 29, as had the defendant's wife when the child was born. Their statement in this respect was borne out by the record, for the defendant's wife suffered very serious complications, which endangered her life and caused the death of her unborn child.

For the reasons assigned, the judgment of the trial court was affirmed.—*Cohen v. Wiggin (La.)*, 178 So. 270.

Insurance, Accident: Varicose Veins in Relation to Death from Thrombosis Following Accident.—In an accident insurance policy issued by the defendant company to the insured, there was excluded from coverage any "accident, injury, disability, death or any other loss caused wholly or partly, directly or indirectly, by disease or bodily or mental infirmity or medical or surgical treatment therefor." On Nov. 7, 1935, the insured was injured in an automobile accident. His seventh and eighth ribs on the left side were broken at a point in line with the arm pit and he sustained a bruise on the inner side of the left thigh and a wound on the left knee. The insured was afflicted with varicose veins in the area of the bruised portion of the left leg. On the fifth day after the accident, the injured part of the left leg became inflamed and ice packs were applied. By November 19 the inflammation and soreness had subsided and the condition remained without much change until the death of the insured on November 22. The plaintiff, as beneficiary under the policy, brought suit to collect the benefits provided in it. The U. S. district court gave judgment for the plaintiff, and the defendant insurance company appealed to the U. S. circuit court of appeals, seventh circuit.

The insurance company contended that the death was caused wholly or partly by bodily infirmity. An autopsy disclosed the broken ribs and a consolidated area in the lower portion of the left lung which, according to the testimony of a medical witness, could be caused either by pneumonia or by a blood

clot. The first possible cause was rejected because of the absence of other symptoms which are present in pneumonia. In the bruised area of the left leg near the enlarged varicose vein there was found a blood clot, which was removed. "It was a rather slippery formation which filled the blood vein like a cast fills a mold." One end of the blood clot was tapered off in a smooth fashion and the other end terminated abruptly and showed rough edges, indicating that there may have been more of it at one time. One physician testified that an incomplete thrombus indicates that one end is missing and has been carried to a new location in the body and that in his opinion the cause of the death was a breaking off of a portion of this blood clot and its final lodgment in the lung. Three medical expert witnesses testified in the case. The conclusion of one was "I believe if the injury had not been there and that vein had not been damaged, the likelihood of the thrombus forming would have been very remote." Another testified "My opinion is that a varicose condition is predisposed to trauma and that injury may set up a thrombus in that leg." Another witness testified that a blood clot is formed in different ways, one being "an injury that damages the wall of the blood vessel." The attending physician testified that in his opinion the thrombus did not exist in the leg at the time of his first examination of the insured following the accident and that, in his opinion, "the bruise is a causative factor of the thrombus because a damaged blood vessel is cause one for blood clot formation."

There were two facts, the court said, which were significant and not disputed. First, there was no thrombus in the varicose vein or that area before the accident. Secondly, there was only a possibility of a thrombus occurring in the varicose vein in the absence of the injuries sustained. In short, the injury must have caused the thrombus to form in or near the varicose vein. While the bodily infirmity need not be the sole cause of the death to defeat recovery under the policy, the court pointed out, it is well settled that the "cause" as here used, either sole or partial, refers to something other than a disease or affliction rendered more serious by the consequences of the accident. If the accident brought about conditions from which death resulted, the fact that the insured was ill, aged or infirm, or had bodily or mental infirmities, would not bar recovery, provided the accident excited the bodily infirmity into activity and death resulted. If the infirmity alone would not have caused death, it cannot be said to have caused death when the immediate result was occasioned by an infirmity which became active only because of the accident. The circuit court of appeals concluded that the testimony was sufficient to support a verdict that the injury was the proximate and sole cause of the death. The judgment for the plaintiff was therefore affirmed.—*Scanlan v. Metropolitan Life Ins. Co.*, 93 F. (2d) 942.

Vaccination: Term "Vaccination" Means Inoculation Against Smallpox.—The defendant was convicted of failing to cause his children to attend a public day school and appealed to the Supreme Judicial Court of Massachusetts.

In September 1935 each of the defendant's children had been permitted to enter the public day school on a certificate signed by a registered physician that the physical condition of the child was such that his health would be endangered by vaccination, such a certificate being required for admission to school of an unvaccinated child. The rules of the school committee required that an unvaccinated child must renew such a certificate every two months in order to remain in school. Such a requirement has been held lawful. *Spofford v. Carleton*, 238 Mass. 528, 131 N. E. 314. Shortly before Jan. 4, 1936, the school authorities notified the defendant to renew the certificates or have the children vaccinated. He did neither but continued to send the children to the public school. Each day, however, they were refused admission by the school authorities, because there was neither a renewed certificate nor vaccination.

The statutory obligation, said the court, to cause children to attend school involves an obligation to put them into condition to attend and cannot be escaped by neglect to qualify them for attendance. The burden of the argument for the

defendant was that the words "vaccinated" and "unvaccinated" do not convey the idea of inoculation against smallpox as distinguished from other diseases and that therefore the statute requiring vaccination as a condition precedent to school attendance was too vague for enforcement. The word "vaccination" was originally used to describe, the court said, the method discovered by Jenner late in the eighteenth century of inoculating with cowpox for the purpose of procuring immunity from smallpox. In the second volume of General Laws of Massachusetts, published in 1823, the earliest statute for compulsory inoculation "with the cowpox," enacted March 6, 1810, was indexed under the word "vaccination." In 1855 a law was enacted which required that all children should be "vaccinated" before attaining the age of 2 years and before being admitted to the public schools. In the statutes of Massachusetts, the court said, and even in common speech, the word "vaccinated," without explanation or qualification, means inoculated against smallpox. The language of the statute was therefore not vague but clear. The judgment of conviction was affirmed.—*Commonwealth v. Childs (Mass.)*, 12 N. E. (2d) 814.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Neoplasm Studies: IV. Clasmatosis in Melanoblast. C. G. Grand, New York.—p. 394.
Distribution of Lead in the Cat After Intravenous Injection of Colloidal Lead Preparation and Effect of Irradiation on This Distribution. B. L. Crawford, H. L. Stewart, C. E. Willoughby and F. L. Smith 2d, Philadelphia.—p. 401.
Anterior Pituitary Gland in Tumor-Bearing Rats. J. Heiman, New York.—p. 423.
Culpability for Delay in Treatment of Cancer. G. T. Pack and J. S. Gallo, Paterson, N. J.—p. 443.

Carcinosarcoma.—Saphir and Vass believe that most of the so-called carcinosarcomas are neither collision nor combination tumors but most commonly are primary carcinomas. The individual cells either show what has been called morphologic variation or have been distorted by chronic productive inflammatory changes within or close to the tumor. In some instances a primary sarcoma had invaded nonmalignant epithelial structures forming inclusions which led to the erroneous diagnosis of carcinosarcoma. Occasionally a so-called carcinosarcoma could be interpreted as a primary carcinoma which had invaded a benign tumor of the connective tissue. A number of carcinosarcomas reported in the literature can be interpreted on the basis of morphologic cellular variations. Transitional cell carcinomas, because of the fact that some of the tumor cells are spindle shaped, are sometimes erroneously referred to as carcinosarcomas, particularly in tumors of the larynx, lungs, esophagus, bladder and urethra. A number of other reported carcinosarcomas are seemingly primary carcinomas complicated by chronic productive inflammatory changes. Malignant tumors, when altered by inflammation, tend to assume indifferent structures in which most of the original features are lost and from which it is usually hazardous to attempt to reach any conclusion regarding histogenesis. Inflammatory changes are most marked in those organs exhibiting cyclic changes, such as the uterus, breast and thyroid; conversely, those organs are more commonly the site of these tumors. Chronic inflammatory changes with fibrosis and many lymphocytes may suggest a tumor of the connective tissue or occasionally a lymphosarcomatous element in primary carcinomas. Chronic productive inflammatory changes are not necessarily confined to "carcinosarcomas" but are present in many malignant tumors. The inflammation seen in the latter, however, is more commonly acute or chronic exudative in character rather than of a long-standing, chronic productive type, such as is almost invariably seen in "carcinosarcomas," particularly in the linitis plastica type of carcinoma. Because of the occasional difficulties in differentiating malignant carcinomatous cells from the cells of young benign tumors of the connective

tive tissue, and because of the presence of giant cells in some of these instances, the cells of tumors of the connective tissue were interpreted as portions of a sarcoma. Because of the pressure of the fibers of tumors of the benign connective tissue the carcinoma cells secondarily become altered, are compressed and resemble sarcoma cells. Close inspection of the histologic pictures accompanying the case reports invariably lead one to believe in the carcinomatous nature of these cells.

American Journal of Ophthalmology, St. Louis

21: 723-842 (July) 1938

- Filter-Passing Agent as Cause of Endophthalmitis. J. S. Friedenwald and Clara M. McKee, Baltimore.—p. 723.
Effects of Sulfanilamide as Determined in the Eyes of Rabbits. V. C. Rambo, Boston.—p. 739.
Irradiation of the Eye and Protective Devices. M. Cutler, H. L. Jaffe and A. Grossman, Chicago.—p. 747.

Contact Lenses with Spheric Optic and Aspheric Haptic Part. F. Nelson, Colorado Springs, Colo.—p. 775.

Sulfanilamide in Gonorrheal Ophthalmia.—The Fernándezes used sulfanilamide in the treatment of eight adult cases of gonorrheal ophthalmia. The diagnosis was established by the clinical picture and the presence of gonococci in the exudate stained by Gram's method. All the patients were treated in the dispensary without hospitalization. A daily dose of 2.6 Gm. was regularly employed during the first three days, divided into four doses of 0.65 Gm. On the fourth day a daily dose of 1.95 Gm. was given, 0.65 Gm. being administered three times a day. All patients recovered in a spectacular manner and in a shorter period than that required by other accepted forms of treatment. The results obtained warrant the judicious use of sulfanilamide in all cases of gonorrheal ophthalmia in adults whenever there is no serious contraindication. Smaller doses and special precautions must be used for patients with renal insufficiency, because the excretion of sulfanilamide is slow and in such patients would tend toward accumulation of the drug in the blood.

Rheumatic Erythemas: Critical Survey. H. Keil, New York.—p. 2223.

Sympathectomy for Hypertension.—Allen and Adson state that 311 operations have been performed on 156 patients by neurosurgeons at the Mayo Clinic without an operative death. Information relative to blood pressure and general health following postoperative dismissal from the hospital has been secured in 131 instances. Seven patients have died subsequent to operation but not as a result of it. Cerebral vascular accidents occurred in two patients. Decrease in the blood pressure and increase in the rate of the pulse when the patient changes from the recumbent to the upright position occurs commonly following operation. Both orthostatic hypotension and orthostatic tachycardia disappear at variable times after operation, regardless of the effect of operation on the blood pressure. The percentage of patients relieved (amelioration or complete dis-

appearance) of headache, when the effects of operation on the blood pressure were good, fair or were recorded as failure or temporary, were 100, 80 and 76 respectively. Nervousness was relieved after operation when the effects of operation on blood pressure were good, fair or poor respectively in 80, 66 and 67 per cent of the cases. The percentage of patients relieved of nonanginal pain in the left side of the thorax after operation, when the effects of operation on the blood pressure were good, fair or poor were 90, 75 and 60 respectively. The surgical procedure frequently failed to relieve such symptoms as fatigue and dyspnea with exertion. Both dyspnea and fatigue with exertion tend to disappear as the time after operation increases. Since removal of the first and second lumbar ganglions interrupts the sympathetic pathways to the lower extremities, the function of sweating of the lower extremities is eliminated. When operation produces good results on blood pressure, T waves that originally were inverted in the electrocardiogram may become upright and the transverse diameter of the heart, demonstrated on roentgenograms, may decrease. Tachycardia occurs commonly when the patient stands or exerts himself after the operation but this reaction gradually disappears. Following the operation the feet are warm and dry. If the blood pressure has been significantly decreased by operation the hands may be cold, apparently owing to vasoconstriction in these parts. A few patients mentioned an area of numbness, variable in extent in different cases. Disturbances of intestinal function (periods of from three to four bowel movements daily, with stools of soft consistency, alternated with periods of normal bowel movements) were noted in a number of instances. In many instances constipation was relieved. Flatulence or other evidence of disturbed motor activity of the gastrointestinal tract were uniformly absent. The sexual function of women is not impaired. Dysmenorrhea may be relieved. Menstruation is not influenced. Fertility is not affected apparently, although the response of the blood pressure to pregnancy is variable. Avoidance of pregnancy seems advisable ordinarily. Usually libido and potentia coeundi of the male are not impaired. Men may be sterile but are not certainly so. The effects of the operation on blood pressure are not uniform. They vary from poor to excellent. No infallible method of selecting patients for operation is available. As a result of their experience with extensive sympathectomy for essential hypertension, the authors believe that it is advisable to operate on more patients who have mild hypertension and on fewer patients who have severe hypertension.

Tuberculosis in Hospital Personnel.—According to Myers and his colleagues, since 1929 entering students in three Minneapolis schools of nursing and one school of education have had the tuberculin test administered. Of all the students entering these schools from 1929 to 1934 an average of approximately 23 per cent have reacted positively on admission. The incidence of positive reactors among the probationers has definitely decreased in the more recent years of the study. All students in the schools of nursing who react negatively to the tuberculin test are retested every six months as long as they remain negative. In each of the four schools the incidence of positive reactors definitely increased before graduation. Primary tuberculous complexes developing among student nurses, as manifested by the positive tuberculin reaction, were sometimes traced to other members of the hospital personnel. Therefore it is recommended that all persons employed in the hospital regardless of their capacity should have adequate examinations for tuberculosis. Most frequently primary complexes were traced to patients who had communicable pulmonary tuberculosis. Every patient entering a hospital, regardless of the admitting diagnosis, should be examined for pulmonary tuberculosis in communicable form. When persons are found to have communicable pulmonary tuberculosis coexisting with the condition for which they entered the hospital, it is recommended that they be isolated in the institution and treated for both conditions. In this way the hospital environment can soon be made safe from the standpoint of contracting tuberculosis. When such a program is in effect, members of the personnel should not show any higher incidence of positive tuberculin reactions or of clinical disease than persons in the general population employed elsewhere. Every member of the hospital personnel who reacts positively to the tuberculin test on employment or subsequently becomes a positive reactor has developed the primary tuberculous complex.

In a small percentage, the roentgenogram has aided in determining the location of parts of the primary complexes. The safest procedure from the standpoint of the student nurse is to keep her from coming in contact with tuberculous patients while in training. This can be done with no particular loss to her future efficiency as a nurse. Only graduate nurses should be employed in tuberculosis services, both in hospitals and in sanatoriums, and such nurses should take graduate training in the fundamentals of tuberculosis before engaging in the active care of patients.

Rickettsias in Trachoma.—Thygeson examined trachomatous tissues from Tunis, Brazil and the United States for the rickettsia-like bodies described by Busacca and by Cuénod and Nataf. No minute parasitic bodies other than the elementary and initial bodies of the epithelial cell inclusions of trachoma could be demonstrated. He believes that the formations which the latter observers described as occurring in large numbers in the trachoma follicles are not parasitic but in all probability cell granules and cytoplasmic debris.

Pellagra Treated with Nicotinic Acid: Two Cases. R. France, R. D. Bates Jr., W. H. Barker and E. Matthews, Baltimore.—p. 46.

Hyperthyroidism and Vitamin C.—Lewis determined the urinary excretion of ascorbic acid before and after subtotal thyroidectomy in five hyperthyroid patients on a constant diet. In all the patients the amount of ascorbic acid excreted before operation was far less than normal. Following thyroidectomy the excretion of ascorbic acid increased in all the patients, reaching a normal value in four of the five patients studied. In four of the five patients the urinary excretion of ascorbic acid before thyroidectomy was similar to that observed in scurvy.

Urinary Changes Due to Sulfanilamide.—Strauss and Southworth observed that the administration (to three normal subjects) of sulfanilamide was accompanied by a decrease in the carbon dioxide combining capacity of the plasma, a definite diuresis and an increase in the renal excretion of sodium and potassium. Two dogs showed slight losses of base through renal excretion but not enough to alter the carbon dioxide combining capacity of the plasma even though they received larger doses of sulfanilamide per kilogram of body weight than did the human subjects.

Poliomyelitis Following Tonsillectomy.—The fact that the bulbar form of acute anterior poliomyelitis has been reported following recent tonsillectomy and adenoidectomy has suggested that this procedure might in some manner influence the entrance of the virus. A study of 418 consecutive patients with acute poliomyelitis admitted to the medical wards of the Infants' and the Children's hospitals of Boston adds further evidence as to this possibility and strongly suggests that in those instances in which the operation is of an elective nature it may be advisable to postpone it when poliomyelitis is prevalent. Eley and Flake offer the following information in support of this statement. Of 287 cases of spinal poliomyelitis there were only eight patients with a history of a recent tonsillectomy and adenoidectomy. Of the eight patients, only three acquired it between the seventh and the eighteenth day (the commonly accepted incubation period of poliomyelitis) after the operative procedure. Of 131 patients with bulbar poliomyelitis, seventeen had had this operation performed within twenty days prior to the onset of their illness. Fifteen of the seventeen patients acquired the disease within the usual incubation period. Statistical computations demonstrate that the occurrence of this number of cases within the given period cannot be attributed to chance nor can it be attributed to the usual frequency of poliomyelitis. The clinical observations suggest that, if the patient is harboring the virus at the time of the operation, traumatization of the tissues may enable it to gain entrance to the central nervous system by way of the lymphatic system or the blood stream or perhaps by direct neural extension. The fact that one of the patients acquired bulbar poliomyelitis following adenoidectomy without tonsillectomy would indicate that it is not necessarily the latter operation which enables the virus to gain entrance to the central nervous system.

Drugs Transmitted Through Breast Milk.—Tyson and his associates studied the transmission of barbiturates and bromides by breast milk in lactating mothers. A total of 164 samples (15 cc.) of breast milk was collected from mothers receiving barbiturates. Chemical analyses of individual specimens of milk after administration of barbiturates in half grain (0.03 Gm.) doses at stated intervals, although amounting in the aggregate to 2 grains (0.13 Gm.) in a day, do not show as high a percentage of positive reactions as do similar specimens after the administration of 1½ grains (0.1 Gm.) at bedtime. Thus, concentrated doses seem to have more effect on

transmission than do cumulative doses. In only two of the forty-one cases was there any clinical effect of the drug on the child, and thus there is the possibility that the child may be affected by the breast milk after medication of the mother with barbiturates. A total of thirty-eight specimens of breast milk was analyzed after the administration of bromide and thirty-seven gave positive results after chemical analysis for the drug. Clinical evidence of transmission was manifested in the child to a marked extent in four cases, although in every case there was a marked diminution in the irritability of the child as well as of the mother.

Epidemic Myalgia or Pleurodynia.—Macdonald presents the clinical and laboratory observations in seventy cases of epidemic myalgia in children, although persons of all ages were attacked during the epidemic. Diagnosis depends on the character of the pain and fever and is extremely difficult except in the presence of an epidemic. In children the disease may be easily confused with acute appendicitis, but the absence of localized pain and tenderness and the relatively low leukocyte count may aid in the diagnosis of epidemic myalgia. In myalgia there is in addition no localized abdominal muscular spasm. Differentiation from pleurisy is difficult in the patients complaining of pain of the chest. In these cases, however, a pleural friction rub cannot be demonstrated. Treatment of the attack is symptomatic. The patients recover rapidly if not treated, but salicylates may be of value in allaying pain. There are no records of death from the disease. Epidemic myalgia, like acute anterior poliomyelitis, occurs during the summer. Accompanying the present epidemic of myalgia the same community suffered an epidemic of benign lymphocytic meningitis.

Metal Fume Fever and Its Prevention.—The metal fumes which produce fever are most commonly encountered in industries in which metal, such as zinc, is heated in an oxidizing atmosphere to a temperature near its boiling point (zinc 930 C.); for example, in the founding of brass and the oxyacetylene welding of galvanized iron. They may also occur during the melting, stirring and casting of brass. Sayers avers that fumes also result from the fusing of manganese in the manufacture of steel, from cadmium in spelter works or during the melting

of cadmium ingots, from smelting and electrolytic recovery of zinc, from antimony in the printing trade and from the vulcanization of rubber. The metallic oxides commonly given off in the form of fumes or dust in welding processes may originate from several sources—from the materials welded, from the coatings of the surfaces being welded or cut, from the coatings of the electrodes used in arc welding or from the flux rods. Because of the temporary nature of the disease, and, since the patient recovers within a relatively short time, only symptomatic treatment is customary. Metal fume fever may be eliminated through the adoption of an adequate medical and engineering program. In order to control the toxic fumes at their source, operations giving rise to metal fumes should be carried on when practicable in airtight apparatus; that is, a closed process. The usual method, however, is to employ exhaust ventilation with hoods over the process producing the fume. The mechanical ventilation is generally more reliable and satisfactory. The ventilating system should be designed so that a current of clean air is drawn past the operator and away from him toward the work. Masks and respirators to be used for workers exposed to metal fumes should be specially constructed and adapted to the material used by such workers.

Bile Salts in Peptic Ulcer.—Bergh administered iron bile salts orally to thirty-two unselected patients with duodenal, gastric or gastrojejunal ulcer established by roentgenoscopic and roentgenographic examination. All patients were ambulant during treatment. The iron bile salts were given four times a day in doses of 0.65 Gm., with each meal and at bedtime. In a few cases in which the dose (2.6 Gm.) produced an unde-

sirable catharsis the dose was cut to the limit of tolerance. Twenty-six patients, or 81.25 per cent, were definitely improved, while six patients were not improved. Many of the patients who had suffered from ulcer symptoms for years were highly gratified because of the improvement experienced. Ten patients experienced increased distress for periods of three or four days up to two weeks. This may have been due to a local irritative action of the bile salts. A week or ten days after starting the treatment, sometimes more and sometimes less, improvement usually became manifest and gradually progressed until many patients felt entirely well. They soon found that they could eat many foods which had previously caused them distress, and they were glad to return to a general diet. However, many patients still found that the ingestion of greasy or highly seasoned foods might be followed by some degree of discomfort. It also was possible for patients to resume work of a moderately strenuous nature, and some patients were capable of returning to heavy labor. X-ray evidence of healing came more slowly than the clinical improvement, and in the early follow-up examinations it was not unusual to find a niche still present, in spite of the fact that the patient was feeling well, was taking a general diet and had returned to work. Later, however, the niche diminished or vanished, giving x-ray evidence of healing in conformity with the clinical improvement.

Zinc Peroxide in Mouth Infections.—Wintrop used zinc peroxide in treating ten cases of acute Vincent's infection, eight cases of chronic Vincent's infection, twelve cases of acute gingivitis, three cases of suppurating periodontoclasia and two cases of radiation necrosis. Zinc peroxide is quite stable and comes not as a pure salt but contains from 45 to 50 per cent of zinc peroxide, from 35 to 40 per cent of zinc hydroxide and from 10 to 15 per cent of zinc carbonate. Only the "medicinal grade" should be used and it must be heated to 140 C. in quantities of not more than 500 Gm. for four hours, to effect sterilization, in accordance with the manufacturer's specifications. Zinc peroxide with 7.5 per cent of available oxygen, nearly as much as sodium perborate, loses its oxygen slowly. Therein lies its great virtue for the treatment of oral infections. Zinc peroxide has a pH of 8.8 and remains stable over a long period, giving up its oxygen so slowly that great amounts of it can be utilized to permeate interstices, crypts and pockets, in which organisms associated with all types of gingivitis, pyorrhea, osteomyelitis and necrosis of the soft tissues abound. Further, the zinc oxide residue is bland and healing and this is an added desirable characteristic. Best results are obtained when the zinc peroxide is applied as a paste. Following application of local medication, zinc peroxide is used by the patient at home every three hours for the first twenty-four to forty-eight hours and then every four hours. It is recommended that the zinc compound be mixed with water to form a creamy paste. One-half teaspoonful for each application is sufficient. This paste is applied by the patient with his finger or on a sterile swab and massaged gently into the interproximal spaces between the teeth and along the gingival margin. The zinc peroxide thus is placed directly in contact with the tissues and remains there for a long time, giving off its oxygen. No effort should be made to rinse the mouth and, as the powder is slowly mixed with the saliva, the patient should expectorate this residue. Patients are seen every other day for further local treatment; the zinc peroxide is continued until complete healing has taken place, and then for another week as an added precaution.

Nervous Complications of Measles.—Cole points out that the pathologic changes of nervous complications of measles appear to be identical with those occurring in postvaccinal encephalitis and in the forms of encephalitis following other acute fevers (mumps and chickenpox). The clinical manifestations have been summarized by Ford (1928). He distinguishes six groups: (1) mild and transient diffuse cerebral symptoms, (2) multiple focal or diffuse lesions of the nervous system, (3) single focal cerebral lesions (aphasia or hemiplegia), (4) cerebellar syndromes of varying degrees of severity (generalized ataxia, intention tremor, loss of muscle tone, slow or scanning speech and nystagmus), (5) paraplegia and spinal cord syndromes and (6) toxic psychoses and papilledema. A case of the postfebrile variety of measles encephalitis is presented. There was no rash. The encephalitis occurred in a mother of two children after mild attacks of measles in the children. The condition began with multiple focal and diffuse lesions and later concentrated on the cerebellar functions. The sequels were minimal, affecting only cerebellar function, and were unaccompanied by mental defects or personality changes. The possible differential diagnosis of acute disseminated sclerosis was excluded by the mental symptoms in the acute attack and by the absence of any further development in over a year. Whether the illness followed an atypical attack of measles without the rash can be less certainly stated.

Vitamin C in Urine in Psychoses.—Minski and Constantine estimated the vitamin C content of the urine in fifty patients after they had been hospitalized for some weeks, by which time the regular hospital diet would exclude any errors which might have been caused by underfeeding before admis-

sion to the hospital. The average daily output of the fifty patients was on the low side, being approximately 9.16 mg. of ascorbic acid in twenty-four hours, while the average excretion of ten members of the staff who were on comparable diets was 14.6 mg. No definite conclusions can be reached, but the weight of many of the patients was on the low side, and whether there is any relation between the weight of the body and the excretion of vitamin C is a matter for further investigation.

Blood Transfusion with Heparin.—Knoll and Schürch investigated the possibility of simplifying the technic of transfusion by the use of heparin to such an extent that it could easily be carried out by a general practitioner without special apparatus and an experienced staff. To samples of 10 cc. of human blood, some in paraffined and some in unparaffined test tubes, 20, 30, 40, 60, 80 and 100 inhibiting units of heparin were added. After various periods the state of the blood was tested with a glass rod. The same blood without heparin was used for comparison. The time of coagulation was found to be increased approximately in proportion to the amount of heparin added. A series of transfusions was carried out in which the blood withdrawn in the Merke apparatus was treated with 1,000 inhibiting units of heparin per hundred cubic centimeters of blood, the heparin being diluted with saline solution to 20 cc., mixed and injected. All the transfusions of from 150 to 500 cc. of blood carried out in this manner, some with paraffined, others with unparaffined, Merke containers, were completely successful and free from complications. The sole advantage that this method has over the citrate method is that paraffined vessels can be dispensed with. Therefore the authors turned to the method of Hedenius (1937) of heparinizing the donor. They determined the coagulation time of their patients from fifteen to thirty minutes after the intravenous injection of increasing doses (measured by inhibiting units) of heparin, the doses being diluted with saline solution to 20 cc. in order to ensure a slow and regular injection taking about five minutes. Experiment showed that doses of 1,500 inhibiting units of heparin increased the coagulation time and this increase was almost doubled by using 20,000 units and about trebled by using 40,000 units. The maximal effect was attained from fifteen to thirty minutes after the injection; there was always a fall ninety minutes after the injection and after two and one-half hours normal values were again reached in every case. The increase of the coagulation time was small in comparison with that observed in vitro. Large doses of heparin must be used when the donor is being heparinized because lesser amounts will not delay the coagulation time sufficiently. In none of the transfusions were there any disturbances in the recipient, and in particular no increase in his coagulation time, so that this method would seem suitable when the recipient is subject to the likelihood of increased bleeding. The donor's blood will have an increased coagulation time for two hours after the withdrawal of blood and he should be careful during this time.

*“Healthy Expectorators” of Tubercle Bacilli. F. Meersseman.—p. 50.
Hemorrhagic Aplastic Anemia Following Gold Therapy. M.-P. Weil,
V. Oumansky and L. Langlois.—p. 78.

“Healthy Expectorators” of Tubercle Bacilli.—Meersseman reports the histories of two young men, aged 24, who had tubercle bacilli in the sputum although careful clinical and roentgenologic examinations always remained negative. The animal tests that were made with the tubercle bacilli detected in the two patients remained negative, but otherwise the bacilli had all the characteristics of the tubercle bacillus. The author thinks that although the detected organisms were true tubercle bacilli their virulence was low. The tubercle bacilli found in the third person whose history is reported produced tuberculous lesions in one of the two guinea pigs in which the suspected sputum was tested. The author further examined, by means of the Ziehl-Nielsen method, the sputums of eighty-four medical students who were free from radiologic and clinical signs of pulmonary tuberculosis. In nine of the students the sputum was found to contain bacilli that were resistant to acid and alcohol. Each of these nine suspected sputums were injected into two guinea pigs. Whereas in eight cases both guinea pigs gave negative results, in the ninth case one of the animals presented tuberculous lesions. The last-mentioned patient was kept under careful observation for three years but no signs of tuberculosis developed. The author further reports the results of investigations carried out on the sputums of eighty young soldiers who were free from clinical signs of tuberculosis. In this group again, one of the animals on which the sputums were tested showed tuberculous lesions. Observation of the patient from whom this sputum was derived proved that this was a convalescent carrier of tubercle bacilli. Later the author made a third series of systematic examinations on medical students and soldiers and he gives the clinical histories of the four who were discovered to be expectorators of tubercle bacilli. During the following year (1935) the author conducted a fourth series of investigations on sixty-five subjects who, on the basis of clinical and radiologic examinations, could be regarded as healthy. After citing some of the reports that other authors had published in the course of these years, he evaluates the different observations and opinions. He says that the detection of tubercle bacilli in the expectoration of apparently healthy subjects has given rise to two theories: (1) Either the apparently healthy subjects who expectorate the tubercle bacilli really have pulmonary tuberculosis, but in the form of lesions so small that they give rise neither to clinical nor to the roentgenologic aspects, or (2) it is an elimination of bacilli by a healthy pulmonary parenchyma without concomitant or consecutive tuberculous evolution. If the latter view is accepted, the origin of the bacilli remains to be explained. The author concludes that the phenomenon which is produced in the “healthy expectorators” represents in reality the first stage of pulmonary tuberculosis of the adult, which may or may not progress actively. From the point of view of the prophylaxis of tuberculosis the author says that “healthy expectorators” do not present a great danger.

*Vaccination by Means of Diphtherial Toxoid and Prophylaxis of Diphtheria. G. Ramon.—p. 1049.

New Conception of Mechanism of Death from Burns. L. Christophe.—p. 1054.

Prophylaxis of Diphtheria.—This report is dedicated to the fiftieth anniversary of the discovery of the diphtheric toxin by E. Roux and A. Yersin and to the passage of the French law (on June 2, 1938) which makes antidiphtherial vaccination with anatoxin obligatory. Ramon points out that fifteen years has elapsed since he first demonstrated that the diphtheric toxin of Roux and Yersin, by the simultaneous action of formaldehyde and heat, can be transformed into an absolutely inoffensive product, which retains its immunizing action. He

discusses the method of vaccination; namely, the dose, number and spacing of the injections, also the method of combined vaccinations, which is based on the employment of a mixture of two or several anatoxic vaccines, for instance, of diphtherial and tetanic anatoxin or even of antityphoid vaccine and of diphtherial and tetanic anatoxins. He shows that these associated vaccinations offer the double advantage of realizing several immunizations at one time with an increased efficacy for each of them. Further he reviews the influence of vaccination with toxoid on the morbidity and mortality of diphtheria in France and in other countries, showing that wherever anatoxin vaccination has been widely employed the diphtherial morbidity and mortality have greatly decreased. Finally he discusses the principles of and the practical indications for toxoid vaccination in the individual and collective prophylaxis of diphtheria. Regarding the law which makes antidiphtherial vaccination obligatory in France, he says that in his opinion antidiphtheria vaccination should be employed during the second year of life. Three injections should be given at intervals of fifteen days. A first injection of renewal is made during the sixth year. Concerning the associated injections he says that, since there is hardly any individual who from childhood is not exposed to the risks of tetanus, it is advisable to employ a mixture of diphtheric and tetanic anatoxins. In this manner, antidiphtheric and antitetanic immunizations are achieved by one series of vaccinations.

Interstitial Nephritis Complicated by Nephritic Changes. E. Schmid.—p. 284.

Influenza in Nurslings.—Geldrich regards influenza as a disease which is caused by an ultrafiltrable virus but says that this virus infection is in the majority of cases secondarily complicated by a bacterial infection. This accounts for the two stages that can be differentiated in the clinical course of the influenza. The primary stage is caused by the virus infection, whereas the secondary stage is the result of the accompanying bacterial infection. Simple uncomplicated influenza of nurslings appears under two forms, the abortive one and the ordinary one. The complications of influenza can be classified into mild and severe forms. On the basis of two case reports the author discusses the forms with mild complications and the forms that take a chronic course. From the forms that have an anatomic basis he differentiates those that are of a purely functional character. The vital functional disturbances of influenza in nurslings are toxicosis, cardiac weakness, gastric and intestinal disturbances, hepatic and renal insufficiency and finally the disturbances of the central nervous system. Regarding the toxicosis the author says that, although in the majority of cases it is of bacterial origin, it may occasionally be elicited by the primary virus infection. Discussing the cardiac weakness, the author differentiates the fulminating form from the ordinary acute form. The fulminating form of cardiac weakness represents an almost complete collapse of heart and circulation, in which the usual cardiac stimulants fail and only the intravenous injection of strophanthin may still be of help. The acute form of cardiac weakness takes a less rapid course so that the organism usually still has time to develop its reserve powers and to mobilize its compensatory mechanism. In his evaluation of the gastrointestinal disturbances that occur during influenza in nurslings, the author says that in some of the milder cases the retardation in the intestinal activity is due to a temporary accumulation of gas in the intestinal tract or to an increased bacteriologic decomposition. These disorders are as a rule easily influenced. The severe forms, however, which are usually refractory to therapeutic measures, represent a more or less complete intestinal paralysis and frequently are a sign of imminent death.

Primary Tumor of Mediastinum in Child, Aged 7 Years. Santyan y Velasco Suello.—p. 542.

Treatment of Meningitis with Serum.—Naccari states that the therapeutic action of antimeningococcus serum depends on the amount of bacteriotropins contained in the serum and on the specificity of the bacteriotropins for a given type of meningococcus. Bacteriotropins are more specific for meningococcus of the type which is used in the preparation of the serum than for other types. The author reports twenty-one cases of epidemic cerebrospinal meningitis in infants and children of Palermo. The patients were treated with serum prepared with strains of meningococci which were isolated from patients in the same city. The serum was administered generally through the spinal route and in some cases through the ventricular route. It was given daily in large doses up to from 100 to 206 cc. and in rare cases 380 cc. The treatment lasted from eight to thirty days and in rare cases forty days. The treatment was discontinued when clear cerebrospinal fluid appeared. Early administration is important. Five of seven patients in whom the treatment was started in the course of the first week of the disease recovered. In the remaining patients in the group the treatment began from the tenth to the twentieth day of onset of the disease. In all the cases which ended in recovery the improvement was manifest following the first few injections. Twelve of the patients recovered. The author calls attention to the fact that the percentage of recoveries is twice as great in patients treated with antiserum prepared with local meningococci as in those treated with antiserum prepared with meningococci from other places. He points out the advisability of preparing the antiserum in different cities for local use.

Bronchiectatic Bronchiolitis: Clinical and Roentgen Study. C. Scarinci.—p. 666.

Physiologic Cholecystography.—Impallomeni points out the importance of stimulating bile secretion in visualizing the gallbladder in cholecystography. He followed the behavior of cholecystography as it was done by Graham's technic or after administration of an intravenous injection of a mixture of either bile salts or liver amines and the opaque substance. The mixture was prepared by adding either 10 cc. of a 20 per cent sodium dihydrocholate solution or 3 or 4 cc. of the preparation of liver amines to 30 cc. of the opaque substance. The author carried on his work in two groups of persons, normal and those with hepatobiliary diseases, the number not being specified. The tests were performed during a fast. The author concludes that when Graham's technic is resorted to the gallbladder of normal persons is visualized in two hours as a small clear shadow, the size and darkness of which gradually increase. Distention of the gallbladder and elimination of bile by the structure early in the course of the test do not take place. The gallbladder of normal persons is visualized within fifteen minutes in the course of the combined cholecystography by bile salts in the opaque substance. By the end of the first hour it is entirely visible. By the end of the second hour it is as clear as after eight or ten hours when Graham's technic is used. Bronner's test, after the administration of two or three egg yolks, empties the gallbladder in the same manner and length of time as Boyden's meal does during the Graham

test. Cholecystography by the combined method of liver amines in the opaque substances gives clearer and quicker results than those obtained by Graham's technic but more slowly than those obtained with bile salts.

*Treatment of Toxic Diphtheria with Vitamin C and Hormone of Adrenal Cortex. J. Dieckhoff and K. Schüler.—p. 936.

Vitamin C and Blood.—Barbier directs attention to reports by other investigators in which it was claimed that, following the administration of vitamin C, an increase in the reticulocytes is noticeable in the blood. However, he also cites an author who failed to observe this increase in reticulocytes following the administration of considerable quantities of vitamin C. In contradistinction to other investigators, he was unable to detect a greatly increased flooding out of reticulocytes into the blood stream following the intravenous injection of vitamin C. Further, he takes up the reports about the favorable effects of vitamin C on leukemia, pointing out that daily injections of ascorbic acid supposedly effected normalization of the leukocyte count in cases of myeloid leukemia. He then describes studies on the blood picture of three patients with lymphatic leukemia and of one patient with myeloid leukemia who were treated with a vitamin C preparation at his clinic. In all these patients he failed to observe a reduction of leukocytes following the treatment with vitamin C.

Adrenal Cortex and Vitamin C in Diphtheria.—Following a brief review of the literature on the combined administration of vitamin C and adrenal cortex extract in toxic diphtheria, Dieckhoff and Schüler say that since the summer of 1936 they resorted to this treatment also in the severe cases of toxic diphtheria. They employed it in addition to the customary serotherapy. They observed that the auxiliary hormone and vitamin therapy failed to influence the general condition, the development of myocarditis, the postdiphtheric paralysis or the mortality of patients with severe toxic diphtheria. In none of the ninety-three cases was it possible to observe an effect on the circulation, particularly on the impairment of the cardiac muscle. However, the hemorrhagic diathesis of toxic diphtheria was to a great extent prevented by the endocrine-vitamin therapy.

Histamine Content of Organs During Serous Inflammation. H. Kaunitz, R. Neugebauer and E. Schweiger.—p. 627.

Nutritional Edema.—Luckner says that the food taken by persons who acquired nutritional edema had a high fluid content but was deficient in caloric value; the protein and fat contents were low, while the carbohydrate content was relatively high; the mineral content was generally high but the vitamin content was low. It was suggested that, in addition to the caloric insufficiency of the diet, the lack of a certain essential constituent in the diet might be responsible for the pathogenesis of nutritional edema. Some suggested that deficiency in fats was the causal factor, while others suggested protein deficiency or lack of vitamins. By an inadequate diet he produced nutritional edema in rats and then compared the symptoms in these animals with those in human subjects. He was able to demonstrate similarity in the essential points. In studies on the

etiology of nutritional edema, he found that the addition of vitamins A, B₂, C and D has no influence on the formation of edema. The addition of vitamin B₁, however, retards the development of edema. This retardation is explained by the significance of vitamin B₁ for the processes of resorption in the gastrointestinal tract. In feeding the animals with rations consisting chiefly of carrots and turnips, edema formation follows regularly. After prolonged feeding with cabbage, edema develops occasionally; but in the course of feeding with kohlrabi, edema was never observed. By adding 0.5 per cent of casein to the basic diet of carrots, edema can be prevented and slight growth can be observed in the animals. If only 0.25 per cent of casein is added, edemas develop after from ninety to 100 days. The addition of the amino acids aminoacetic acid, asparaginic acid, tyrosine and tryptophan has no influence on the pathogenesis of nutritional edema. However, edema formation is prevented by the addition to the food of small amounts of cystine and glutathione. The efficacy of cystine is probably due to the fact that the cystine content of the protein of the basic diet is inadequate for the formation of the plasma protein. The decrease in the colloid osmotic pressure connected with this deficiency of plasma protein results in the formation of edema. In summarizing the observations, the author reaches the conclusion that nutritional edema is caused by malnutrition with biologically deficient protein. By causing a disturbance in the resorption of food, deficiency of vitamin B₁ may accelerate the appearance of the edema.

*Hemangioma of the Vertebral Column. I. S. Rosentsweig.—p. 47.

Hemangioma of the Vertebral Column.—According to Rosentsweig, hemangiomas of the vertebral column are benign vascular neoplasms developing frequently on the basis of a congenital anomaly of the vascular system. The great majority of these tumors are found accidentally at necropsies. Hemangiomas only rarely give rise to clinical manifestations. They are capable, however, of producing a clinical picture of compression of the spinal cord. Of the five patients observed by the author, four presented symptoms of spinal cord compression. The diagnosis of hemangioma of the vertebral column is possible only on the basis of roentgenologic examination. Hemangiomas causing compression of the cord may be treated by operative intervention or by roentgen irradiation. The former has a higher mortality because of profuse bleeding. Roentgenotherapy has been widely used in this condition with gratifying results. The author reports a cure in three of his four cases so treated and an improvement in the fourth.

*Diagnosis of Myocardial Infarct with Aid of Thoracic Leads. R. Langendorf and A. Pick.—p. 80.

Etiology of Chorea Minor.—Edgren points out that the most widely accepted opinion on the etiology of chorea minor is that it has some connection with a rheumatic infection. Bacteriologic examinations of the brain, the spinal fluid and the blood of patients with chorea minor have yielded diplococci, staphylococci and streptococci. The pathologic-anatomic aspects of the brain vary; embolisms, congestion and small hemorrhagic foci have been observed. Moreover, attacks of chorea minor have been known to alternate with attacks of acute polyarthritis or endocarditis, and infections of the throat,

measles, scarlet fever and influenza have been suspected of a connection with chorea minor. Other investigators have suggested dysfunction of the parathyroids and psychic or physical traumas as causal factors of chorea minor. The majority of investigators regard hereditary predisposition as an important factor in the development of chorea minor and the author himself reports the case of a girl with chorea minor who had three siblings who were also subject to these attacks. Moreover, the mother of these siblings had had attacks of chorea gravidarum in the course of several of her pregnancies. Discussing the erythrocyte sedimentation speed of patients with chorea minor, the author says that in a large percentage of these patients it is either normal or slightly increased. He reaches the conclusion that the etiology of chorea minor has not been fully explained as yet. Many factors indicate that chorea minor is not a definite disease entity but rather a syndrome with various etiologies. Hereditary predisposition probably plays an important part in the etiology.

Arterial Hypertension and Hypophysial Hormones.

Van Bogaert and van Baarle point out that in recent years several investigators have attributed an important role to the hypophysis not only in eclampsia but also in certain forms of hypertension. After reviewing some of the studies on the presence of hypophysial hormones in the cerebrospinal fluid of patients with pregnancy toxicoses or of patients with hypertension, they report their own investigations. They aimed to determine whether in patients with hypertension the cerebrospinal fluid contains (1) the gonadotropic principle of the anterior hypophysis and (2) a vasopressor principle of the posterior hypophysis. They examined the cerebrospinal fluid of nineteen patients. They do not feel justified in drawing generalizing conclusions from their observations on a comparatively small number of patients, but they observed that the cerebrospinal fluid of men or women near the menopausal age, with or without signs of renal insufficiency or signs indicating impairment of the arterial system, did not contain hormones in a quantity sufficient to elicit maturation of ovarian follicles in impuberal mice or rats. On the other hand, in a case of eclampsia in which hypertension was accompanied by signs of ovarohypophysial dysfunction such as obesity and hypertriehosis, the cerebrospinal fluid had folliculizing power. The questions arising from these observations are whether the presence of folliculinizing hormones in the cerebrospinal fluid of the second type of subjects is not directly related to their dysendocriniasis and whether hypertension is only an accidental phenomenon in these cases. In further studies they aim to show that only those patients with hypertension who also have hypophysial disorders have folliculinizing substances in their cerebrospinal fluid. They think that patients with simple hypertension have neither folliculinizing nor vasopressor substance in the cerebrospinal fluid.

Thoracic Leads in Diagnosis of Myocardial Infarct.

Langendorf and Pick studied the electrocardiographic records of forty-four cases of myocardial infarcts of the anterior wall and of twenty-three cases of the posterior wall. They compared the electrocardiographic records in which the leads were taken from the extremities with those in which thoracic leads were employed and found that among the cases of myocardial infarcts of the anterior wall, and rarely also among those of the posterior wall, there were some in which only the thoracic lead permitted a diagnosis, whereas the leads from the extremities revealed either no changes indicative of myocardial infarct or such changes as were not sufficiently characteristic to permit a diagnosis. Conversely, there are rare cases in which thoracic leads fail to disclose a myocardial infarct of the anterior wall, whereas the classic leads (extremities) reveal the characteristic aspect of myocardial infarct. From these observations the authors conclude that the leads from the extremities and from the thorax are complementary and that it is erroneous to think that the thoracic leads alone are sufficient for the diagnosis of infarcts of the anterior wall and the leads from the extremities for the diagnosis of the infarcts of the posterior wall. To be sure, they admit that in individual cases of infarcts of the anterior wall the thoracic leads are frequently superior to those of the extremities.

A School Health Program

DON W. GUDAKUNST, M.D. DR.P.H.

State Commissioner of Health

LANSING, MICH.

The greatest public health problem of this country is to supply adequate medical care to the people. This is not a problem of any one social, geographic, economic or age group. It is universal. Studies made by various agencies all reveal the need for more and better medical care. The condition is a challenge to the public health and medical authorities. It is not my purpose to discuss the various proposed and attempted methods claimed to afford a solution of the condition, nor is it my purpose to do more than superficially analyze certain aspects of the problem. But I shall point out one of the ways whereby, here in Detroit, we are meeting this need.

There are in this community more than two thousand physicians licensed and qualified to practice medicine for nearly two million people. There are hospitals, dispensaries, welfare agencies, city physicians and various social and political arrangements all aimed at supplying medical care to the various groups at a price they can pay. There are enough doctors, there is enough wealth. There is enough ability to render good medical care to all at all times. People should have a doctor whenever they need one, whether that need is for alleviation of suffering, prolongation of life, cure of disease or prevention of sickness and preservation of health. Yet this utopian state of health, this ideal condition of the practice of medicine, is far from being reached. Why is it that we have a community with enough of everything medical and with a fair amount of wealth, and yet on the one hand many are without medical care and on the other the talents and skill of physicians are wasting because of lack of patients? Why is there needless sickness and premature death? Why are physicians denied their opportunity to serve?

There can be no simple answer. No single explanation will suffice, nor can any revolutionary change in methods of practice guarantee the desired results. It is certain, no matter what

the whole picture may present, that one phase of the problem has to do with education. This is one of the basic, fundamental points. If the people knew the real value of medical care; if they but knew the need for utilization of the skill and abilities of physicians as applied to their own case; if they knew how, when and where to secure such care; if they knew the value received by buying and paying for medical services, then most assuredly our problem would be brought much nearer solution. The details of distribution of services and compensation for them could be more readily worked out if the people only knew what, when, why and how they should buy medical care. As a result of this lack of knowledge the problem, then, becomes one primarily of education. Our schools are the places which provide education. Hence, develop a school program and at once the whole thing is done. So simply stated, so easily perceived but so very difficult to achieve!

Time does not permit of delving into the history of more than four decades of school health work in this country, interesting as it might be to do so, nor can I any more than point out some of the obvious failures that have resulted from having certain types of medical services and health programs in our schools.

HEALTH SERVICE TO CHILDREN

Everything that is done in the schools has a certain educational value, just as every living experience of the child develops certain attitudes toward life and initiates or establishes certain practices and habits. Let us look briefly at some of the practices and analyze their end results. In many states and cities, school work has been highly developed along lines of service to children. The most casual inspection revealed children in need of medical care. Teeth were decayed; tonsils diseased; eyes, ears, hearts, lungs all needed medical treatment; children were without protection against diphtheria and smallpox. In short, children were in a bad way.

The World War reemphasized this condition. More and more money was poured into school medical services; more teeth were pulled and repaired, more examinations done, more eyes refracted; chest clinics and heart clinics were established; and so on through the whole gamut of the practice of medicine. The health of the next generation of adults had to be improved and protected at any cost. All this was very laudable, but what happened? As the result of parent-teacher association activities, summer round-up campaigns were inaugurated for youngsters about to enter school. In droves by the hundreds of thousands they were taken to school to have their physical examination by the school doctor or well intentioned private physicians; states passed laws compelling the schools to give annual or periodic examinations to all school children. The schools vaccinated all children because of compulsory vaccination laws; diphtheria prevention treatments were as much a part of the school routine as reading or writing instruction; preschool children, as well as adults, were urged to utilize these immunization clinics; extensive dental services were introduced; nurses, health teachers, gymnasium instructors, science teachers all told children what to eat, how and when to sleep, what to wear, how to play and exercise; we brushed the teeth and blew the noses for the children, all in the name of health education. And what happened? Maybe we did save lives, maybe we did remove tonsils, get glasses, repair teeth, cause children to gain weight, but what did we teach in respect to health? We taught the child and his parents to turn to the school as the source of all health guidance and counsel. We created a dependency on this arm of the state in respect to health. We assumed a load of obligations in the school too great to carry. There developed a distrust and disrespect for school physicians which undoubtedly, in the minds of the public, was directly transferred to no little extent to a distrust and disrespect for all physicians. We taught the child to depend on a type of service that was to be denied him when he was graduated from or left the schools. We were trying to treat a symptom of social sickness and not the cause. The defects of children, and not the cause of these defects, received our attention. We were engaged in a mopping-up process and not a prevention program. It was not until recently that a realization of all this has been effected. It was not until recently that any real effort has been made to use common sense in our school health programs and really teach both the needs of medical care and the means of securing such care. Detroit has pioneered in this field. Detroit is attempting to attack the basic health problem through education. The school, the public health authorities, the medical men have united in their efforts to establish a sound program.

If the people know the need for medical care, if they know where and how to secure it, and if they are given good value for the money they spend, the problem would be largely solved, even to the care of the medically indigent. Tax and charity supported institutions and programs will be inaugurated and operated for the needy if the people know the value of medical care. Tax appropriating bodies cannot afford to refuse the demands of an intelligent population; they cannot afford to refuse adequate compensation for medical services to indigents.

When the problem is looked at from this point of view, school health service and school health education programs become something far more than looking after a comparatively small section of the population. Then, truly, care and thought must be put into the health plans for the schools if our objective is to be education of the community in order to have complete medical care rather than merely building an emergency service for children of school age.

TEACHING THE NEED FOR MEDICAL CARE

Let us trace the activities of the Detroit schools in respect to certain of their services and see how well they fulfil their obligation to teach people the need for medical care as well as how to secure such care in our community as it is organized today. There is first the physical examination program. During the past few years physical examination blanks have been given to all the children entering a school for the first time. In certain of the schools and at the kindergarten and first, seventh and tenth grades, such blanks are given to all children in the class. These are designed for use by the private physician in order to allow him to report to the school the essential points about which the school has need to be acquainted. The school must know certain things about the children in order to conduct properly its teaching program and activities with the maximum efficiency and with the least possible danger to the individual child. Particularly must the school know about the hearing, vision, heart, nutrition and general health of each child. But it needs to know about such things as orthopedic defects and hernia if the child is to be a candidate for athletic activities. It must know about the communicable disease history and protections if groups are to be placed together and still be assured of a minimum of contagion and pestilence. For the child's own good, early defects must be discovered and corrected. These are all sound practices—and these reasons have allowed schools the world over to employ school physicians to make the necessary periodic physical examinations; but again let it be emphasized that when the school makes this examination it but teaches the child to turn to the school for this service. If it is granted that such an exami-

nation is advisable, it must also be admitted that the best place to secure such an examination is at the hands of the man who is to give continued and additional advice relative to this child and his health, and from one who is ready and able to carry out any corrective procedures that might be indicated by the examination. This means that the examination should be done in the office of the child's own physician—be that private physician or clinic. The question has been asked "Why not make such an examination compulsory? Compel every child to go to his own doctor for such services. If it is good for one, it must be good for all." The answer is simply that this is a program of education. You cannot compel people to learn nor can you compel them to live a healthy life. Compulsion would do more to defeat the plan than would having the services rendered all children every year in schools by state or city employed school doctors. We want to teach the people to go to doctors for services they want because they think and know that these services are worth while. Last year more than 20,000 children went to about 1,500 physicians for their own school examination. There is no means of computing the amount of money spent for this or the ultimate amount of good that was done and will continue to be done for these children. During the present year it is to be hoped that this number will be increased by at least half; 35,000 children served by their own doctors because that many children and their parents have been convinced that such services are worth seeking.

This by no means represents all the vast number of children who should have such care—that would be all of the more than 330,000 children in the public and parochial schools. But for the rest a different technic is used—they are the ones from families who do not think this is worth spending money for. The school teachers here play their part. For the past sixteen years the teachers in Detroit schools have been engaged in conducting a special examination of their students. We all appreciate the need for teachers and schools examining children as to their knowledge and educational advancement in reading, writing and spelling, but it is not so universally appreciated that schools need to conduct the same sort of examination of the children in respect to their health knowledge. If a child knows enough to go to his own physician and return to school a report of the results—that child "passes"—he is examined no further by the teacher. But for the remainder there is no measure of their health practices and knowledge unless some type of examination is made. Hence, each year the teacher inspects all the other children for the presence of certain physical defects—vision, hearing, teeth, tonsils, cervical glands, thyroid, posture, nutrition, skin. She has been trained to do this inspection the

same as she has been trained in other methods of educational diagnosis. She wants to find those children who have failed to look after their own health. She wants to find those who need special education. This she can do. Accept my word for it that her work is highly accurate, that she is not doing medical staff work but merely that of a school teacher. Those children who are found to have gross defects that apparently should be in the hands of a medical man are subject to a second type of examination aimed at measuring their knowledge of good health practices. Remember, this teacher is not primarily concerned with the discovery of pathologic conditions but with children who are in need of medical attention and who do not know the need of it or who do not know how to get it if they do realize the need. If the child has an obvious defect and is actively under the care of a physician for that particular fault at the time, there is nothing more that the school needs or can do about it. But if those defective eyes, ears or tonsils or if that faulty nutrition or thyroid is not immediately under a doctor's care the school is almost compelled to do something about it, for here is a very important fault in the education of the child and his family—here is a child in a family that does not know there are things medical needing to be done which can be done. The parents are invited to come to school to discuss the health of this child. Thus far the teacher is on safe ground, for she has been dealing with observation of facts. But the minute she attempts to tell parents what should be done about the disease and health of the child she steps over into the field of the practice of medicine. This she cannot do; hence physicians are employed to meet with these parents who have been invited to school to discuss the health problems of their own children.

EDUCATIONAL TASK OF THE PHYSICIAN

The school physician takes up the educational task at this point. He meets from ten to fifteen parents in a morning. He examines those children who have been shown by the teachers to have physical defects for which they are not receiving medical care. He demonstrates these defects to the parent; he points out the need for medical care and, what is most important, he carefully instructs the parents how to secure such care. It is not his task to give the care or even to advise the kind of care needed. He is concerned with pointing out the need for and way of securing care. This advice cannot be routinized in any manner—it must vary to meet the individual situation. Usually it consists of telling the parents to return to their regular attending physician. At times, for certain classes of patients, it consists of discussion of the proper use of free clinics. Again it may be made up of an explanation of one or more of the various plans set up by the Wayne County

Medical Society, the city or the state to assist people in securing medical care. His work is purely educational—education given by members of the medical society, directed at those very persons who, as the result of the teacher's diagnosis, are found to be in need of such directed teaching.

A word about these school physicians. They are for the most part young men and women—graduates of the best schools—having had the best of hospital training and well recommended by their fellow practitioners. They are in no sense of the word political appointees. They must meet the highest standards of training and personality, for they are placed in schools to represent the practice of medicine to the very group that needs to be convinced that medicine has something to offer them. These school physicians are appointed to the staff for a period of but two years, approximately one hundred of them serving at any one time, fifty new to the work each year. This rapid turnover is deliberately done in order to acquaint an ever increasing number of physicians with the needs of the school child, with the vast amount of corrective work that must be done, with the methods of "selling" medical services to parents who are reluctant for one reason or another to have such service, and to acquaint the practicing medical profession with the facilities of the school aimed at furnishing an education for the handicapped children.

CONTROL OF COMMUNICABLE DISEASES

The control of communicable diseases in school has long been one of the major problems of the school health staff. When the situation is looked at in a fair, impartial manner it must be admitted that much of the effort that has been expended in the past has been entirely wasted. It was for the purpose of control of contagion that physicians were first placed in schools about a century ago. But contagion went merrily on its way. The theory used was all wrong. To place an army of doctors and nurses in school to detect sickness after it had occurred and after the child had come to school can be of no avail, for we are dealing with contagious and communicable conditions. The sick child has no business in school. Yet this simple thought does not seem to have been appreciated until a late date. In fact, today it is the exceptional school system that does appreciate it. The child who comes to school with any form of sickness represents a family lacking in knowledge of how to care for the child and how to act best to protect the health of the public. Placing a staff of diagnosticians in school would only tend to increase the desire of parents to send their sick children to school. Why shouldn't they send the child to school to find out what is wrong with him? But the minute that is done there is the start of a new epidemic. The sick

child does not belong in school. Parents can be taught to keep such children home. When they do slip, it is the duty of the teacher to detect such slips as indications of the need of further education. Because of this need, teachers conduct an inspection each morning of their students. This is not a formal medical examination but merely observation of the children to see whether any are sick. If there are such they are sent to the school nurse, who passes on those that show signs of communicable disease. These children are then taken home; an explanation is given the mother as to what she has done to her child and how she has exposed other children of the class. Further, it is the duty of the teacher or of the nurse who takes the child home to instruct the mother what she should have done—how she should have called in medical advice before sending her child to school in an obviously ill state. She is advised to call in her own physician for treatment, but the school, through the board of health, sends a diagnostician to the home as soon as possible so as to establish immediately a true diagnosis and allow for the prompt institution of control methods within the school. Much criticism has arisen over this point. We seemingly are working at cross purposes here. The school and the department of health should not have to interfere with the physician-patient relationship. But parents who thoughtlessly and needlessly send a child who has scarlet fever, measles, whooping cough or any other communicable condition to school cannot be trusted too far. They cannot be expected to do the entirely right thing of immediately calling their own physician for all too frequently the child does not appear too sick. He has either a very mild condition or a very early stage of a serious state. Obviously the former is usually the fact, for the child did not feel too sick to go to school. And the school must have an immediate report—delay of a day may mean the development of a serious outbreak. The only alternative to sending a physician to the home of every such case would be having one in school (as is still done in many cities), and this would take us right back where we started—teaching the people to turn to the school for medical diagnoses and advice.

IMMUNIZATION

I need no more than mention the other phase of communicable disease control as carried out in our schools—immunization. We are entering the tenth year since a dose of diphtheria prevention treatment—toxin antitoxin or toxoid—was given in any Detroit school, yet nearly 90 per cent of the school children have had one or more series of treatments. Diphtheria has ceased to be a major threat and has become so since we discontinued diphtheria immunization as a school project. As long as the school engaged in administering these treatments just

so long did the people turn to the school for this type of care, and as long as they turned to the school just so long did they neglect to have the preschool children protected. Thus in the year before our present method was established there were more than 100,000 school children given protective treatments. But there were also 450 deaths from diphtheria—most of them of preschool children. Through our well intentioned efforts we had advertised the need of protecting the school child against diphtheria to such a point that the preschool child was neglected. In the minds of the people there was the thought that this was a disease of the school age, for if it were not so then why did the school pay so much attention to it and why did the school see fit to set up elaborate and expensive clinics for its control? Hence the rank and file of parents waited until their children were in school before granting them protection. The result was 450 deaths a year. Now we are greatly perturbed because during the year just passed there were a few more than twenty deaths of Detroit people. There were no more because parents have learned to take this responsibility on themselves—because parents have taken their children, long before school age, to their own doctors for protection. Diphtheria has not been eradicated, but it has been controlled in a way that would not have been possible if mass immunization programs were carried on in the schools.

So too with smallpox. While we have not completely eliminated the vaccination of children in our schools, the amount of service has been greatly reduced. Each year that which is done in the schools is less and less. Education of the parents as to the need for vaccination—education of the parents as to how to secure this service—has left but 5 per cent of the entire school population to be cared for by the school doctors.

Schools no longer are the place of epidemics that they once were. While it is not possible to eradicate disease of a communicable nature completely, the number of cases has been reduced most markedly. Parents have learned to keep their children home when sick. They are learning to call in their own doctors; children are protected by their own physicians against certain diseases, not because the children are forced or herded into this action but because they and their parents know that this is the cheapest and safest course of action to follow because they and their parents have learned that money spent for this type of service returns large dividends both in health and in money.

The modern concept of school health programs cannot for a moment stop or start with the four walls of the school. Schools are but a part of the community. The value of the school and its educational program depends on how

well they are focused on community needs. School health studies, the examination of children, measuring the amount of communicable disease, and the amount of disease prevention treatments that have been given but reflect the needs of the entire community. If we find that 8 per cent of the students are in need of dental care, then we have a community lacking in adequate dental care for the rest of the population. If there are a large number of pupils with uncorrected vision in the school, then we have a community with need for additional attention to the eyes. The proportion to which defects are found in school children reveals the thinking of the community. School children are but samples of the population and show the level of health education operating in the home. When the school looks on its health problems as being expressions of lack of appreciation of the value of good medical services, then a real challenge and a real opportunity are afforded the health and medical authorities.

The school is not an organization set apart from the rest of the social structure; the cultural, educational, social and health backgrounds of the component families determine the school needs. Obviously, if this is true only the most superficial effort is made to secure improved living if the activities are limited to the school itself. The poor health conditions of school children are symptoms of community ignorance of good health practices.

OBTAINING COOPERATION OF PRACTICING PHYSICIANS

Not only does the school need to educate its students and teachers, but its program should be aimed directly at reaching others not ordinarily considered as an integral part of the school system. One of the most essential community agencies is the medical profession as represented by the practicing physicians. When there is antagonism existing between private physicians and the school doctors, dentists, nurses or teachers, then the school is in error. When such a condition unfortunately exists, the school has failed to elicit the cooperation of the very group charged with the responsibility of health supervision and care. There can be no misunderstanding on this point. The physicians who object to and fight against the school and its practices may in individual instances be wrong, but the error rests with the school in not preparing these physicians to play their role and in not including them in the picture. It is in error in not taking their problems, rights, and points of view into consideration. Physicians will approve and assist in the school health program when they understand its aims and objectives, together with the various steps taken in achieving these ends. They will lend their full support when the school refrains from doing those things that should be, and can well

be, cared for by the practicing physicians of the community. They will aid the school in carrying out those phases of the program that can be handled only on a group basis, when they are afforded an opportunity to see that it is only through such methods that the general health practices of the community can be raised.

To this end here in Detroit we have taken a long step forward. No longer are the health department and the board of education the only groups concerned with building and carrying out school programs. I wish to pay tribute to the wise policy of actively including the Wayne County Medical Society in the picture—included not merely as a figurehead but as an active planning force, a group originating ideas, a group carefully measuring and considering the effectiveness of the steps that have been taken. To the School Health Committee, as a part of the Medical Economic Commission, goes the

credit. This committee has been not merely a buffer to shield the director of school health service of the Detroit Department of Health, as has been occasionally charged; it is rather a committee composed of representatives of various branches of the practice of medicine, well leavened with training in the science and art of public health, working out details of programs as well as main ideas. Further, it is the task of this committee to see that the practicing medical group knows what the plans are and in what way it can assist in carrying out these plans. Thus there is more nearly certain assurance that not only will the health needs of Detroit's school children be met, not only will the level of health practices be raised for the entire community, but also that in so doing the practicing physician will be afforded wider scope for service with all the concomitant benefits accruing to him.

Comments and Reviews

SURVEY OF TUBERCULOSIS AMONG MEDICAL STUDENTS

Many reports have appeared from student health services of universities indicating that tuberculosis is the main occupational hazard of medical students. In a survey, the Tuberculosis Committee of the American Student Health Association found that in the school year 1934-1935 the incidence of tuberculous disease was 5.7 per thousand in seventeen colleges having an active program for the detection of tuberculosis. In three colleges having no programs, with an enrolment of 13,000 students, the incidence of tuberculous disease was 1.2 per thousand.

At the University of Minnesota, Myers found that about 100 per cent of the graduating classes of the schools of nursing and medicine had positive tuberculin reactions. Less than 50 per cent of the other schools of the same university fell in the same category. Soper and Wilson studied the students entering Yale in 1931. Of the undergraduates, 53.3 per cent reacted to tuberculin; 67.7 per cent of graduate students reacted. Of the latter, those entering law reacted in 57.8 per cent; those entering medicine reacted in 76.9 per cent. At the University of Wisconsin, Stiehm studied the tuberculin reaction of all students enrolled during the school year 1933-1934. The average incidence of positive reactions was 29.9 per cent, while among the medical students 44.7 per cent of the freshmen and 55 per cent of the seniors had positive tuberculin reactions. At the University of Pennsylvania in the school year

1930-1931, tuberculin testing showed that there was an average of 85.6 per cent positive reactions among undergraduate students, while the medical students averaged 93.6 per cent positive reactions, with a steady increase from 84.8 to 98.2 per cent in the successive four years.

These surveys show that medical students acquire tuberculous infection to a greater extent than do other students.

ACTUAL TUBERCULOUS DISEASE

Soper and Wilson studied the entering class of 1,644 students at Yale in the fall of 1930. Among the forty-four entering medical school, 4.5 per cent showed latent adult type tuberculosis while only 1.3 per cent of the rest of the students showed a similar condition. At the University of Pennsylvania in 1930 the incidence of obvious pulmonary tuberculosis among medical students was found to be 1.02, 0, 3.1 and 7.4 per cent for the four years. In the school year 1935-1936 at Pennsylvania, 1,024 students were roentgenographed in the undergraduate and graduate schools, uncovering six cases of pulmonary tuberculosis (0.58 per cent). In the medical school in the same year the incidence was 0, 0.8, 8.02 and 12.8 per cent for the four years, the average being 5.8 per cent.

At the Phipps Institute the incidence of apical tuberculosis among college students of ages 17-21 varied from 1.5 to 6.7 per cent. Among the medical students between the ages of 21 and 26 the incidence varied from 4.9 to 30.3 per cent, with a steady progression with age. Another survey by the same group of men showed that the incidence of apical tuberculosis in medical students varied from two to five times that of dental and law students.

In comparison are statistics gathered from a questionnaire which the committee sent to all medical schools in the United States. The incidence of positive tuberculin reactions among students in medical schools in the East showed a definite increase throughout the four successive years. The percentage of positive reactions in the first year classes varied from as low as 20 to as high as 85. In the graduating classes of the same schools the percentage was in all cases greater than 80, the average being 91.5. Reports from the Middle West indicated that the average would fall at not greater than 50 per cent for the four years. No results were obtained from the Far West. In the South the average for four years exceeded 60 per cent, the tendency being for higher rates to be reported from the sea coast district and lower rates from the mountains. These results substantially agree with those previously recorded as to three factors: (1) the high incidence of positive tuberculin reactions among medical students, (2) the progressive increase of tuberculin reactions with successive years of the medical course and (3) the high incidence along the Atlantic coast and lower incidence in the Middle West.

In four Eastern schools with adequate programs for detection of tuberculosis, the incidence increased steadily from the freshman to the senior class. The minimum incidence was 0 per cent, which occurred only in freshman classes. Three of the four reported the maximum incidence in the senior year. The average for these three schools was 7 per cent for the senior year. Figures from New England, the Middle West and the South showed little progression from year to year as the percentages were quite low in each class. A representative figure is that of the University of Michigan, where over a period of years the average incidence has been 0.52 per cent for the freshman class and 0.42 per cent for the senior class, the average for the four years being 0.36 per cent.

The situation is alarming. The statistics given are those of schools where the most reliable programs are in operation. Undoubtedly the incidence in medical schools in general is not nearly this high, but statistics as furnished by some thirty schools could not be included because of their incompleteness. On the other hand, many of the schools have no adequate program for the detection of tuberculosis, and it is fair to assume that those schools from which replies were not received are to a large extent delinquent in this matter.

PREDISPOSING FACTORS

In a study of this sort it is necessary to discover whether it is the individual or the environment which differs from the normal. The questionnaire issued by the committee

included requests for information about any correlation found between the development of tuberculous disease in any given individual and the family history, the individual history, the extracurricular work and housing facilities. One school found a correlation of 18 per cent between the family history and the development of tuberculosis in its students.

There were no reports which would indicate that a preexisting lesion was definitely a cause of tuberculosis in the same student while in medical school.

Six schools reported a tendency for extracurricular work to have a part in tuberculosis in medical students. One school reported that 60 per cent of the cases of tuberculosis were in students who did extracurricular work.

Less than one fourth of the schools reported that they have control of housing facilities for the students, which includes adequate health inspection of the proprietors and other employees. The remaining three fourths have no control over housing facilities. Only one of the schools had compulsory physical education.

Thus far there is no evidence on which to base a belief that predisposing factors have an important part.

SOURCES OF INFECTION

The committee feels that there is sufficient evidence indicating that, at least in the group under discussion, exogenous reinfection is extremely important. Of the sources of infection that have been suggested, the most important are contact with tuberculous patients and classmates, necropsy rooms, boarding and fraternity houses. In addition, bacteriology laboratories have also been indicated.

Dr. Stiehm at Wisconsin reports that among nineteen girls living in a sorority house one had been troubled by a cough for three months before consulting a physician, who then discovered that she had far advanced tuberculosis. Fifteen of the other eighteen reported for tuberculin tests, and of this group eleven had been previously tested and were negative. Of the eleven known negative reactors 100 per cent were now positive. The one individual showing a negative test had been living in the sorority house for only two weeks. Two of these girls subsequently showed active lesions, necessitating withdrawal from school.

In a report by Diehl and Meyers at the thirty-second annual meeting of the National Tuberculosis Association, contact with other students and exposure to tuberculous patients were felt to be the important factors in a study of the case histories of students who had acquired tuberculosis.

DIAGNOSIS

Physical examinations are not sufficient to diagnose early cases of tuberculosis. A routine

case-finding program is indicated if early cases are to be disclosed. In a survey made by this committee of methods used in colleges and medical schools, some procedures were suggested which should be included in the ideal case-finding program. Such a program should include the Mantoux test or some other method of testing sensitivity, x-ray examination of positive reactors at periodic intervals and retesting of negative reactors at periodic intervals, followed by x-ray examination if they become positive. Any person having roentgenographically demonstrable lesions should be further studied by laboratory methods with regard to the sputum, blood sedimentation rate, differential blood count, temperature variation and gastric contents.

Forty-one of the seventy-seven medical schools to which questionnaires were sent have responded. Of the forty-one schools, twenty-eight have an active program. Of the twenty-eight schools having a program, it is available to every student in each school. In twenty-one of the twenty-eight it is compulsory. In the remaining seven from 33½ to 100 per cent of the students availed themselves of the service, indicating that medical students too are blind to their own advantage.

Thirty of the schools have a student health department which, in twenty-six cases, administers a tuberculosis program. All the student health departments carry out routine physical examinations each year on entering freshmen, and some on all four classes. Seventeen of these departments apply tuberculin tests to entering freshmen. In all but two, negative reactors are retested periodically. Seven carry out the retest at yearly intervals, three at four month intervals, and the rest repeat the test in the senior year or at irregular intervals. One school, instead of using the Mantoux test as a filter, roentgenographs all the entering freshmen, while another school uses the fluoroscope as a routine in the same manner.

X-ray examination is applied in twelve schools to all freshmen before attending classes. Three additional schools roentgenograph their tuberculin positive freshmen. Six other schools roentgenograph all students each year, and one applies the fluoroscope in the same manner. Fourteen schools roentgenograph all tuberculin positive students every year and fourteen schools roentgenograph all new tuberculin reactors as soon as the reaction becomes positive. Six schools apply the x-rays during the senior year to the graduating class.

Data gathered at the University of Pennsylvania show that when symptoms were regarded as a sufficient warning 32 per cent of the cases were incipient, 55 per cent moderately advanced and 13 per cent far advanced. With the insti-

tution of routine chest roentgenograms an additional 60 per cent of cases were diagnosed in the incipient stage.

PROPHYLAXIS

Prophylaxis of tuberculosis, with particular reference to medical students, is dependent on elimination of all sources of infection as far as possible and general hygiene of the individual. Medical students should strive toward better care of their physical well-being. The student in whose family there is any history of tuberculosis should be especially careful.

To eliminate exogenous sources of infection, the removal of the tuberculous student is important. Of utmost importance is the prevention of infection in the clinics and dispensaries. Myers of Minnesota, and others, advise aseptic technic in the handling of all sputum positive patients just as in handling any other contagious disease.

More sanitary methods would not be amiss in the necropsy rooms: more careful handling of infected organs; disinfection of gowns, gloves and tables, and possibly the wearing of masks by the student during necropsies in advanced cases of tuberculosis.

Boarding houses and fraternity houses should be investigated with reference to tuberculosis among the employees.

In the bacteriology laboratory the use is recommended of nonpathogenic strains which are available for culturing, the use of killed cultures for staining purposes, and obedience by the student to laboratory regulations requiring that loops contaminated with a culture of tubercle bacilli be placed in boiling water for several minutes before flaming. Failure to carry out the last point in handling pathogenic strains can easily provide an inoculum for a whole class.

COST

Where large groups are handled by a well organized student health department, financed by an annual health fee, the actual cost of a tuberculosis program can be as low as \$2 a year per student. Satisfactory results can be achieved by the use of paper x-ray plates with a check up of suspicious cases by celluloid films with the resultant saving of about 50 per cent of the cost of the latter. The fluoroscope can also be utilized to economic advantage, though probably its use is best restricted to persons of slight or moderate build. Whatever the cost, it must be met if there is going to be a reduction in tuberculosis morbidity among medical students.

CONCLUSIONS

It has been shown that medical students are particularly prone to acquire tuberculosis, that they are infected to a much greater degree than other student groups, and that infection and

the development of the disease occur chiefly in the clinical years of their training. The most obvious cause of this is their high degree of exposure to tuberculous patients where sanitary precautions are not observed. It has been demonstrated that a modern case-finding program will reveal tuberculosis in its most easily arrested stage and at a time when ultimate recovery is almost guaranteed. Consequently, the American Medical Students' Association recommends the institution of a case-finding program in all medical schools, and the institution of isolation and aseptic technic in handling open tuberculosis.

WHAT SHOULD THE DOCTOR BE TAUGHT?

We must agree with Aristotle, said W. R. Halliday, LL.D.,¹ principal of King's College, London, that there are other qualities than those which can be tested by examinations which are necessary to the application of medical knowledge. It is common experience that, in some branches of the profession, one who has not been a brilliant student may prove to be a better practitioner than his fellow who has been more successful in academic tests. Can one think of two more different men in the higher walks of medicine than William and John Hunter? William, the fashionable accoucheur, an eloquent orator and a social success; John, incomparably the greater original genius, difficult, rather farouche, and tongue tied to such an extent that before giving his lectures he required to fortify himself with a draft of laudanum. We sometimes confuse the minimum standard of knowledge required for a license to practice and what is quite different, a hall-mark of scientific proficiency and promise. There is work for general practitioners as well as for specialists. These specialist enthusiasts, Dr. Halliday said, are terribly single minded. Long ago, Peter Latham wrote: "Many a great chemist, a great botanist or a great master of analysis may be found to contend that what he has to teach is indispensable to the medical student; that the principles of his science are at the root of all rational practice. But beware of great authorities. They have a tyrannous way with them." In former days, the specialties of the clinical period of study had not developed their modern complexity and multiplicity. It was not unusual then for a doctor to have taken his degree in the humanities before he came to the study of medicine, and this kind of education produced a very fine type, a type which was especially qualified to keep the medical profession in intimate touch with the world of laymen. But whether we deplore it or not, that kind of medi-

cal education has gone for good. The basis of modern medical education is now scientific. One must start with elementary zoology, botany, physics and chemistry on the theory that the doctor to be is to get an idea of the principles of these sciences. There is one school of thought which is working in the direction of teaching these subjects as specially adapted to the brains and requirements of medical students. That, Dr. Halliday said, is wrong. He would like these elements of science to be kept quite disinterested. It is important that the future physician get a glimmering of what these sciences are about irrespective of the art of healing. It is important if he is later to be a specialist that he should have sufficient general grounding to be able to resume and to carry further his studies in the relevant science.

Is the prospective general practitioner to be expected to master every possible method of treatment during his period of study? That is the problem which has to be faced, for as medical science advances the subjects will multiply still further. To try to teach too many subjects in a given time is to have them all imperfectly mastered. It is not a good plan to set up a standard which involves knowing less and less about more and more. I am sure, Dr. Halliday continued, that some at least will consider that there is a real danger of the medical curriculum for the ordinary student becoming overloaded. Surely to turn out good doctors and to advance medical knowledge in the long run does just as much to relieve human suffering as the maintenance of the wards in a hospital.

STUDY OF SYPHILIS AMONG WIS- CONSIN STUDENTS

In view of the national syphilis campaign, the Department of Student Health at the University of Wisconsin endeavored to determine the incidence of syphilis among the college students. An elaborate setup was established to assure the student protection against his identity being revealed when the results were posted, then a post card was sent to every student inviting him to have a Wassermann test made on a certain day. While at first the response was high, it gradually fell off as the novelty decreased, and the total number of tests made finally amounted to only 30.5 per cent of the student population. There were 2,442 tests made on male and 944 on female students. A report of this study has been made by the director of the Department of Student Health, Dr. Llewellyn Cole.¹ A negligible amount of syphilis was discovered. There were only two cases of active syphilis in the group of 3,389 who submitted to the examination, two cases in which there was a persistent 1 plus reaction

1. Cole, L. R.: Survey of Syphilis Among Students at University of Wisconsin, *Arch. Dermat. & Syph.* 38:70 (July) 1938.

and one case in which there was a 2 plus reaction. Six doubtful reactions were reported and on repeated examinations they were still doubtful. The conclusion arrived at from this study coincides with the experience in the care of students at the University Infirmary where among about 2,000 admissions and about 50,000 outpatient visits during the year, one or two is the maximum number of cases of syphilis discovered. Nevertheless, Dr. Cole recommends that the Wassermann test be performed as a routine on each newly entering student and on each graduating student.

INTERN TRAINING IN OBSTETRICS

The Maternal Welfare Commission of the Pennsylvania State Medical Society recently endeavored to secure the opinion of recent interns and of older practicing physicians on the present method of training interns in obstetrics in the approved one year hospitals in Pennsylvania. Dr. Walter J. Larkin,¹ a member of the commission, sent a questionnaire to 200 recent interns. It was not compulsory for the interns to reply to the questionnaire nor did they need to sign their names. Following is an abstract of Dr. Larkin's report on this survey: The first question was "Do you honestly think that your obstetrical training received as an intern qualified you to do obstetrics, unassisted, in the home or hospital?" Among 154 replies, twenty-two answered the question "yes" and 132 answered "no." The second question was "If not, was your service too brief or not properly supervised, or too small, or what?" More than 90 per cent of the replies to this question were to the effect that the service was too brief; 64 per cent replied that the service was too brief and not properly supervised, and 23 per cent responded that the service was too small. Some of the other questions with Dr. Larkin's comments were: Do you think you should have had more difficult obstetrics or more forceps deliveries? Ninety-seven per cent (128) of the answers were "Yes." Many qualified their statements by saying that they would have been satisfied if the cases had been properly discussed and properly supervised, even though they had not been allowed to apply the forceps. One replied that "he had never had a forceps delivery but had witnessed one forceps delivery. Most of them replied to the effect that they did not have enough forceps deliveries for a young man entering a small town practice. How many forceps deliveries did you have? Thirty-four physicians entering practice in the commonwealth of Pennsylvania, in small cities, stated that they had never had a forceps delivery and had never put on forceps. At how many

cesarean sections did you assist? The answers to this question varied from none to twelve. Six did not assist at any.

Dr. Larkin also sent 100 questionnaires to practitioners who had completed their internship within the last ten years and thirty-five questionnaires to physicians who had been in practice more than ten years. Some of the questions and the analysis of the replies were as follows: 1. How much laboratory work do you perform in your office, such as urinalyses, blood counts, blood sugar estimations, Wassermanns, smears, etc.? 2. How much of your laboratory work do you send to the laboratory? 3. If you do laboratory work in your office, of what does it consist? 4. How many necropsies have you performed since completing your internship? 5. At how many have you assisted? Three had performed one or more necropsies; all had been coroners or coroners' assistants. No one in general practice did anything outside of urinalyses and blood counts. Every one stated that he was doing his own urinalyses. Seven physicians responded that they were doing their own blood counts.

The results of this questionnaire prove, Dr. Larkin says, "that there is something wrong with the obstetrical training of the intern and something definitely wrong with the time lost in laboratory training for the intern. The laboratory service which is never used in full when a young man leaves his internship is overemphasized, and too much time is lost in that department. . . . A six weeks period is not sufficient time in which to train a man to do obstetrics." "Yet the commonwealth of Pennsylvania insists that the intern spend two solid months of eight hour days in the laboratory and but six weeks, with no restriction on the number of hours, in obstetrical training."

Claude Bernard's Graduating Thesis

In 1843 Bernard set himself to discover what happens to different foodstuffs in the course of nutrition. He was led to the conviction that phenomena of nutrition can be settled only from the point of view of the chemist. He started with digestion in the stomach, particularly the role of gastric juice. His original contribution was that gastric juice acts upon cane sugar, for he found that if sugar was injected into the blood after it had been acted upon by gastric juice it could no longer be recovered in the urine, whereas if cane sugar alone was injected into the blood it was excreted unchanged. He used these results for the thesis for his degree of doctor of medicine, which he presented in December of this year, throwing in for good measure a few pages on such unrelated topics as hydrocephalus, aneurysms and cupping glasses. He was successful in his defense of this thesis, and in publishing it he dedicated it to Magendie. The completion of his medical course did not fundamentally change his mode of life, except to transfer his activities completely from the hospitals to the laboratory. He never at any time engaged in the practice of medicine.—Olmsted, J. M. D.: Claude Bernard, Physiologist, New York, Harper & Bros., 1938.

Medical College News

Medical schools, hospitals and individuals will confer a favor by sending to these headquarters original contributions, reviews and news items to be considered for publication in the Student Section.

Minnesota Fellows to Study Cancer

The National Advisory Cancer Council of the U. S. Public Health Service has awarded fellowships to Drs. Raymond E. Buirge, Charles B. Craft and Carl J. Lind Jr., all of whom for the last three years have had teaching fellowships and have been taking special training in the department of surgery at the University of Minnesota Medical School, Minneapolis. Under the terms of their new fellowships they will devote from two to three years to the study of cancer.

Annual Expedition to Greenland

Eleven college students were included in the party accompanying Capt. Robert A. Bartlett on his twelfth annual expedition to Greenland, which sailed from New York June 20. The party will make reports on temperatures and water conditions to the Hydrographic Bureau in Washington and will collect specimens for the Cleveland Museum of Natural History and for the Smithsonian Institution.

Lost on the Clipper

Dr. Earl Baldwin McKinley, dean and professor of bacteriology and director of medical research at the George Washington University School of Medicine, Washington, D. C., and Fred Campbell Meier, plant pathologist of the Department of Agriculture, were on the Hawaii Clipper, lost over the Pacific, July 28. They were engaged in research on aerobiology and in making arrangements for the continuation of the collection of micro-organisms, viruses, pollens and dust in the upper air by officers of the trans-Pacific airships.

Associate Wins Trip to Switzerland

Clay Myers Greer, M.S., research associate in pharmacology, Vanderbilt University School of Medicine, Nashville, Tenn., was awarded a prize by the committee on international congresses of the Federation of American Societies for Experimental Biology. The prize will be a trip to the International Physiological Congress in Zurich, Switzerland, in August. Mr. Greer's work was on "Nor-Epinephrine [β (3,4-Dihydroxyphenyl)- β -Hydroxyethylamine] as a Possible Mediator in the Sympathetic Division of the Autonomic Nervous System."

Dr. Code Receives Theobald Smith Medal

Charles F. Code, Rochester, Minn., will receive the second Theobald Smith Award in medical science, it was announced at the meeting of the American Association for the Advancement of Science, June 30. The presentation will take place at the winter meeting of the association. Dr. Code was selected "in recognition of his discovery that histamine is normally present in human blood and when present in abnormal amounts indicates tuberculous infection or an allergic reaction to the presence of foreign proteins in the body." Dr. Code graduated from the Manitoba Medical College in 1934. He entered the Mayo Foundation as a fellow in physiology, July 1, 1934. The Theobald Smith Award, consisting of a bronze medal and \$1,000, was established in 1935 by Eli Lilly & Co., Indianapolis, to be awarded to an investigator under 35 years of age for "demonstrated research in the field of the medical sciences taking into consideration independence of thought and originality."

Intern Wins the Burr Prize at Philadelphia

Dr. Samuel Koppelman received the Charles W. Burr prize for interns at the Philadelphia General Hospital June 30 for a thesis entitled "Effects of Large Doses of Insulin on Blood Hydration in Man." The prize is \$100.

Graduates Accept Reserve Corps Commissions

Forty-five commissions as first lieutenants in the medical and dental reserve corps of the U. S. Army were presented to graduates of the schools of medicine and dentistry of Baylor University at commencement exercises, June 6. Dr. Hardy A. Kemp, professor of bacteriology at the medical school, who holds a major's commission in the medical reserve, was in charge of the exercises and the principal speaker.

Scholarship in Psychiatry

A Woolley scholarship in Paris is offered an American student in psychiatry for the year beginning October 1. The scholarship consists of \$600 and a room in the United States House of the Cité Universitaire in Paris, under whose auspices the offer is made. According to *Nature*, the candidate must be an American citizen. Application should be made to the Institute of International Education, 2 West Forty-Fifth Street, New York.

Mercy Hospital Becomes University Hospital of Loyola

Mercy Hospital, 2536 Calumet Avenue, Chicago, has recently become University Hospital of Loyola School of Medicine, which is on the north side, and will henceforth be known as Mercy Hospital, Loyola University Clinics. Dr. Robert S. Berghoff, Chicago, has been appointed medical director of the institution. Dr. Berghoff is clinical professor of medicine at Loyola. He graduated from St. Louis University School of Medicine, St. Louis, in 1913.

Reunion of Former Interns at Rhode Island Hospital

The second reunion of former interns will be held at the Rhode Island Hospital September 9-10. Dr. Herman C. Pitts is general chairman; Dr. Henry S. Joyce, general secretary and treasurer. The mornings will be devoted to clinics and clinical demonstrations at the Peters House. There will be a five year study of gallbladder cases, demonstration of a vascular boot originated in the hospital, motion pictures illustrating a new method of cystotomy, a demonstration from the gynecologic research department, improvements in orthopedics and fracture treatment, and a demonstration of neurologic methods by former interns who are now members of the staff of Butler Hospital. There will also be a fracture clinic, thoracic clinic, tumor clinic, demonstration of cardiology and a clinical pathologic conference.

On Friday afternoon the papers given by visiting former interns will be read. Dr. Reeve H. Betts of Boston will speak on "Some Aspects of Nontuberculous Thoracic Therapy" and will show motion pictures of various thoracic operations. Dr. Nat H. Copenhaver, Bristol, Tenn., will read a paper on the history of the thyroid. Dr. Arthur H. Morse, professor of obstetrics and gynecology, Yale University School of Medicine,

New Haven, Conn., will read a paper on "Pathology and Treatment of Antepartum Hemorrhage." Dr. John P. Macnie, New York, will present an ophthalmologic subject. Dr. Harold G. Tobey, Boston, will speak on "Allergy" and Dr. James E. Paullin, Atlanta, Ga., on "Cardiovascular Syphilis." This meeting will be held at the Aldrich House Auditorium.

Saturday afternoon a Rhode Island clambake will be served at the Squantum Club.

The Status of Interns in California

The Board of Medical Examiners of the State of California sent a letter to all hospitals in the state relating to the status of interns in hospitals. The board pointed out that the Business and Professions Code provides that no person may practice any system of treating the sick unless he has a valid unrevoked certificate to do so. An exception is made in the code of students regularly matriculated in any legally chartered school approved by the board, provided the treatment is without compensation to the student and is a part of his course of study. This means that interns must be regularly matriculated students in legally chartered schools approved by the board of medical examiners or they cannot treat the sick, and that as interns they are prohibited from treating the sick except as a part of the regular course of study. It appears, the board wrote, that any person not regularly matriculated in a school approved by the board who might treat the sick in a hospital might in so doing bind the hospital for his acts in such a way as to make them guilty of violating the section of the code which states that "corporations and other artificial entities have no professional rights, privileges or powers."

New York Personals

Carlyle F. Jacobsen, Ph.D., assistant professor of psychology at Cornell University Medical College, has been appointed professor of medical psychology at Washington University School of Medicine, St. Louis. Dr. William M. Cahill, instructor in biochemistry at the Cornell University Medical College, has been appointed instructor in the department of physiologic chemistry of Wayne University College of Medicine, Detroit.

Alumni Meetings in Texas

Dr. George W. McCoy, formerly the director of the National Institute of Health, Washington, D. C., was the principal speaker at the recent commencement of the University of Texas School of Medicine in Galveston; his subject was "The Goal of the Future—Better Medical Service."—Dr. Charles Gordon Heyd, New York, formerly President of the American Medical Association, delivered the recent commencement address of Baylor University College of Medicine, Dallas, on "Medicine in a Changing World." Dr. Heyd also addressed a luncheon meeting sponsored by the alumni and faculty of the university; this address was entitled "The Opportunities of a Great Medical Center as Offered by Dallas and the Southwest."

Alpha Omega Alpha Awards

At the annual commencement of New York University College of Medicine June 8 the Alpha Omega Alpha Prizes were awarded to Drs. Robert Franklin Pitts, Milton Sapirstein and Rudolph E. Drosd for the highest scholarship in the fourth year class. Dr. Robert Pelton Wadham received the 1938 alumni award for meritorious service to the university. There were 134 graduates.

Appointments and Promotions at Temple

Recent appointments to the faculty of Temple University School of Medicine, Philadelphia, include the following:

Dr. Michael Scott, associate in neurosurgery.
Dr. Richard P. Thompson, clinical assistant in surgery.
Dr. Jefferson Neale Richardson, clinical assistant in dermatology and syphilology.
Dr. Mason Royden C. Astley, clinical assistant in surgery.
Dr. Thomas A. Campbell, resident in radiology.
Dr. Augustin R. Peale, III, special resident in radiology and pathology.

The following promotions were also announced:

Dr. Lowrain E. McCrea to assistant professor of urology.
Dr. Alexander Silverstein to lecturer on neurology.
Dr. Leon Hugh Warren to instructor in dermatology and syphilology.
Dr. Robert K. Arbuckle to instructor in radiology.

The address at commencement exercises, June 16, was given by Secretary of the Treasury Henry Morgenthau. There were 113 graduates.

Guide Service at Harvard

Guide service is now available at Harvard University Medical School, Boston, and will continue through September 17. During the summer of 1937, when the service was first introduced, about 11,000 visitors were taken through the various divisions of Harvard University.

Medical Care for Students at Maryland

Provision has been made for the systematic care of students in the medical school, including a physical examination of all students during the first week of the semester. A student must pass this examination before he is finally accepted as a student. Students in need of medical attention will be seen by the school physician in his office or in cases of necessity in their homes. If it becomes necessary for a student to enter the hospital during the school year, the medical council has arranged for payment of part of all his hospital expenses, depending on the length of stay and special expenses incurred. This regulation applies only to students admitted to the hospital through the school physician's office. Prospective students are advised to have any known physical defects corrected before entering in order to prevent loss of time. It is especially urged that all new students have their eyes examined and any error of refraction corrected before beginning the course.

Koessler Fellowship Awarded

The Jessie Horton Koessler Fellowship for the aid of research in biochemistry, physiology, bacteriology or pathology has been awarded for 1938-1939 to Ralph E. Kirsch, M.A., who has completed three years of the medical course at the University of Chicago. Mr. Kirsch's study of the control of length of gestation in mammals, with especial reference to the physiology of the placenta and uterus, will be carried on under the direction of Dr. Allen T. Kenyon, assistant professor of medicine, School of Medicine, Division of Biological Sciences, University of Chicago. The fellowship was established in 1930 under a bequest of \$10,000 from Dr. Karl K. Koessler; the income from the gift defrays the expense of the annual award. It is administered through the Institute of Medicine of Chicago.

Maryland Personal

Dr. Lewis H. Weed, professor of anatomy and director of the department, Johns Hopkins University School of Medicine, received the honorary degree of doctor of laws from Duke University at the recent commencement.

OPPORTUNITIES IN PEDIATRIC PRACTICE

CHAIRMAN'S ADDRESS

CLIFFORD SWEET, M.D.
OAKLAND, CALIF.

Pediatrics has much to offer that it did not have twenty-five years ago; but as in all the other specialties in medicine, the number of well qualified practitioners has increased manifold while all recent graduates, whether in some other specialty or in general practice, have had a far better fundamental pediatric training during their undergraduate days than was available anywhere during the earlier years. Thus, while many more children than formerly are getting adequate pediatric care, there is a much greater number of qualified physicians among whom the patients are divided. If one looks uncritically at the practice carried on by an individual physician, therefore, one may think that pediatric practice is going into an early and perhaps fatal decline and one's mind may turn longingly back toward the "good old days" of the pediatric boom. However, I know of no old days which can be called altogether good when one examines them critically enough to compare all their disadvantages as well as their advantages with those of any given later time, unless a dark age has descended in the meanwhile.

During the earlier years it was easy to become a specialist. A good training in medicine, an interest in a certain field of study, a short time spent familiarizing oneself with whatever knowledge others had accumulated, and the ability to teach oneself from observation soon raised one well above the level of one's confrères. The number of physicians with special training was small, and the number of patients needing special care, much of which could now be given by any competent general practitioner, was great, so all the conditions for "the beaten path to the door" were abundantly present. Also, since in that not far distant day the counsel of the family physician, and even more that of the specialist, was sought only under the pressure of dire need, adequate fees could be charged for emergency care and, once they were paid, years might elapse before there was again any drain on the family purse and no concerted cry against the high cost of medical care was heard in the land.

During my undergraduate years (1905-1912) and for several years afterward there were pediatric teach-

ing centers in this country only at Boston, Chicago and New York (listed alphabetically) and the pioneer work of such teachers as Sedgwick at Minneapolis and Porter at San Francisco, while Howland was just beginning his work at Johns Hopkins. In the other large cities of this country pediatric practice and teaching were carried on by one or two men, and most of them had studied in Berlin or Vienna. This was the *eiweissmilch* period of American pediatrics.

With few exceptions pediatrics was taught as a minor subject in the departments of obstetrics and medicine. As an undergraduate I attended lectures by the professor of diseases of children, a general practitioner who confined his remarks almost entirely to diseases, usually without clinical demonstration, and a children's clinic held once weekly at which the attendance of as many as five children was remarkable. How greatly this contrasts with the well organized pediatric department, often one of the best teaching divisions, in all the leading medical schools of the present.

While the larger cities were not so nearly saturated with pediatricians and pediatric ideas were not so generally accepted as they now are, most cities of a size that now support several (from three to six) pediatricians were but little affected by pediatric knowledge. Such communities were ideal for the practice of simple or primary pediatrics. The milk supply was dirty, pasteurization was neglected or ineffective, marantic infants were plentiful and many thrive on mixtures of boiled skimmed milk, water and sugar, fed at regular intervals, and when death took his toll his visit was not altogether unexpected and "God's will" was accepted. Scorbutus was common, and its prompt cure with orange juice aroused more than passing comment. Rachitis was frequently seen in advanced stages, so that the physician had the courage to prescribe and the patient the hardihood to stomach the cod liver oil then available. The diagnosis of pyuria or of otitis media before rupture of the tympanum and empyema, not to mention lumbar puncture, branded one as a specialist indeed. Infants were fed largely on patent foods procured on the advice of neighbors, relatives and physicians. Fortunately the very limitations of such artificial feeding made insistence on breast feeding easier than it is now.

While sick infants were abundant, one had little or no opportunity to give the preventive care and the guidance which it is now known can play such an important part in the care of well infants and children. I had little or no opportunity for systematic care of well infants during my earlier years of practice except as I extended it as a labor of love and a means of study to those infants whose mothers were under

my obstetric care, in the form of the gratuitous and not always welcome advice which I gave while attending a sick infant or another member of the family or on occasions when the baby was brought to my office to be duly admired and his net weight determined because some question had arisen that could not be answered by weighing him while fully dressed at an obliging neighborhood druggist's or grocer's.

Regularity as a basis for child management was a revolutionary idea, often received by the layman with evident amazement that any one could be so foolish as to suppose that any infant could be taught regular habits, and it was regarded by many physicians as an unnecessarily fussy modern notion. So with few exceptions infants slept with their parents and were nursed, fed, fondled, jigged and carried about as fancy dictated. I have often wondered if the rise of golf as a form of exercise may not have had some relationship to the decline of floor walking with an infant in arms during the night.

In the medical centers at that time pediatric practice, while not so limited, was still hedged about by various complicated forms of infant feeding, and the pediatrician was distinguished from his fellow practitioners largely because he alone possessed the basic training in the care of infants and children which has been taught in more recent years to all graduates in medicine.

From many quarters have come grave doubts concerning the future of pediatrics as a specialty in medicine. While those doubts are a natural outgrowth of the changes which have taken place in the fundamental structure called society, of the even more rapid progress which has been made in medicine, including pediatrics, and of human nature when faced by changing conditions, I think it profitable to consider briefly the advantages and the hopeful signs for the future with which such doubts and fears may be offset. Doubt, fear and distrust of an uncertain future are an inescapable part of the thought of all intelligent creatures. The only defense against becoming hopeless and overwhelmed by fear, doubt and distrust of the future is to stop and give time and thought to the courage, the will to live and be happy, the intelligence and the faith which have carried mankind so far above his original bestial state and which are a priceless part of the heritage of each. A philosophy of reasonable hopefulness must dominate the lives of those who are devoted to planning the very foundations on which children are to erect their lives.

REQUIREMENTS FOR A SPECIALTY

Any division of medical practice which is truly a specialty must fulfil two fundamental qualifications. First, it must have a continuing record of accomplishment which could not be an outgrowth of the general practice of medicine, and, second, it must challenge an appreciable number of the best minds in the medical profession to become proficient in its practice and to make ever greater its service to mankind by the addition of new knowledge and practical applications of that knowledge to the needs of men.

Pediatrics fulfils these fundamental definitions of a specialty. Its record of accomplishment is reflected not only by its large part in the diminished infant and child mortality but in better care for and understanding of children among civilized people everywhere, and above all in the greatly increased ability of all practitioners of medicine in all specialties and in general

practice to care for children. In fact, the devoted and unselfish teachers of pediatrics have done their work so well that the very excellence of their teaching has done more than any other one thing to raise doubts concerning the future need for pediatrics as a specialty. And teachers of pediatrics are not alone those who teach and train students, interns, residents and nurses in medical schools and hospitals but every one who practices good pediatrics in the community in which he lives. Any community which has within it a worthy pediatrician becomes a place in which the level of child life rises, because his teaching influences physicians, nurses, dentists, teachers, parents and, not least, the children—for who is so easily quickened to evangelical zeal by new thought as is the child?

That the present level of medical care for children would have risen naturally as a corollary to the general advance of medicine without the labors, research and devotion of the many men and women who have made it their life work is highly improbable. At least it rose sharply in both scope and excellence coincidentally with the birth of pediatrics as a specialty, has continued steadily upward and certainly has not yet arrived at, or anywhere near, the state of perfection beyond which even greater progress is impossible. The problem of fitting specialized medical knowledge and progress to the peculiar needs of the child will always require for its solution persons who give to it their undivided energy and devotion. In the congress devoted to human welfare, whose members are medical specialists, the child must always be ably represented. The future of pediatrics, I am certain, is made secure by the very fact that children have needs which are different from those of adults. The ability best to serve those needs can be attained only through long study and experience by physicians whose principal interest is in children and in whom there resides a peculiar ability, not possessed by every one, which enables them to understand and enter the intimate life of the child, not as an intruder but as a friend.

Another stone which makes secure the foundation is the concern of the pediatrician for the entire life of the child rather than with some part or system which is suspect or out of order temporarily. As in all other human relationships, this advantage carries with it great responsibility and some disadvantages. In a relationship between patient and physician which can be fruitful and grow in influence only if it continues over years there must be real interest, patience and a quality of leadership on the part of the physician that hardly rests on one who successfully performs a temporary, although great, service such as an operation or even obstetric care. Having given much of himself the pediatrician must accept the misunderstanding and ingratitude which are at times his portion with that nobility of the spirit which causes him to search himself for faults rather than accept the ready to hand satisfaction which comes to one who easily places all blame on another.

PREPARATION FOR PRACTICE OF PEDIATRICS

The practice and the problems of pediatrics demand as thorough preparation and offer as many opportunities for study and research as does any specialty in medicine, if not more. The mastery of present pediatric knowledge requires an amount of time, energy and intellectual acuity that compares favorably with the demands of any other specialty. In addition it challenges its followers in certain peculiar ways. Disease

must be detected and studied in its beginnings, when signs and symptoms yield their evidence only to painstaking study, keen observation and sound judgment developed by experience. Here medicine most often yields her choicest gift, prevention. The pediatrician must know as much about all the other branches of medical practice as the internist does; he must know more than those specialists who treat only some parts of the body, and in addition he must become expert in the special knowledge which should govern the application of treatment to children in respect to health, nervous stability and, especially, growth and development.

Growth and development, with all their variations in the individual, have yielded many secrets to intensive study but have many mysteries not yet solved and can never be reduced to the simplicity of an exact mathematical formula. In this field, peculiar to pediatrics though not its exclusive domain, wise, intelligent and constant study will yield marvelous results, although the student will finally have to agree with Robert Louis Stevenson: "Little do ye know your own blessedness; for to travel hopefully is a better thing than to arrive, and the true success is to labor."

Perhaps not the least of the intangibles which the pediatrician must solve arise from the fact that he must gain a large part of his information indirectly through the observations and reports of parents. A nice evaluation of information filtered through the emotions and the often prejudiced, not infrequently poorly articulate, mind of a layman requires experience and long and thoughtful study of the human mind and emotions.

In addition to all other technical training the pediatrician must learn a sound, efficient technic of teaching, the necessity for which is important in the practice of any branch of clinical medicine but most so in pediatrics. He must be able to convince, teach and often inspire the adult members of the family if he hopes to influence effectively the life of his patient, the child.

All in medicine who are worthy of their calling must have an interest in their patients which goes beyond the mere use of technical skill and the material rewards therefor, but the pediatrician must have genuine emotional, I might say spiritual, attachment to children—a concern for their welfare which will always cause him to accept generously as a considerable part of his rewards the consciousness that he has contributed to life at its beginning. True, the practice of pediatrics must yield him a living and the means with which to carry on his work, but if this is his primary interest he might better choose a specialty in which the financial returns per patient are usually greater.

Finally, pediatrics is the only specialty, with the possible exception of geriatrics, which is limited only by the age of the patient cared for. In this distinction lies, I believe, one of its greatest sources of permanence and strength, allowing its followers much latitude of choice in developing their own peculiar abilities and interests and perhaps making it the pioneer on the trail which all specialties will follow during the coming years. By this I mean that the specialist will more nearly approach the relationship to his patients formerly occupied by the general family physician, in that he will have an ever increasing interest in and concern for his patients in all their problems of living, in health and disease. He will then serve them more freely than most now do in the solution of minor problems, and

as now within the limits of his specialized technical training, while he guides and counsels them when they have need for the care and skill of experts in other fields.

ADVANCEMENT OF PEDIATRICS

The principal ways in which pediatrics can be advanced above its present high level are the following: First, of course, the pediatrician must maintain all efforts unabated to protect, understand and enrich the entire life of the child in all its phases, physical, mental, emotional and moral. What greater challenge can there be for any one than that he be a contributor to a generation that has been brought up to face life physically efficient, freed as far as may be of unreasonable fears, with fully developed mental powers and trained in those fundamental qualities of character without which no civilization can long endure? Second, the pediatrician must have a training sufficiently broad and comprehensive to enable him to give children more complete care at reasonable cost. This can best be done on an annual fee basis, and I hope soon to present a detailed paper on this method of carrying on pediatric practice, a method which Gengenbach of Denver found to be quite generally followed in the West but used little, if at all, in other parts of this country. One must remember with Zahorsky¹ that people who have young children are usually at the small income period of their lives. Third, good pediatric care must be extended to rural communities, in many of which there is only a beginning. Fourth, the specialty must give its followers such training that those whose interests and qualifications make them valuable primarily as pediatricians may be able to develop especial ability in the application of other specialized fields of medical knowledge and technic to the needs of children. This means of advance should include the sound pediatric training of the numerous followers of other specialties, many of whose patients are children.

All of these demand certain changes in the procedure of many medical schools and of the societies whose members are specialists. Pediatrics and all the other major specialties in medicine have progressed along similar lines. In all a concerted effort has been made to increase the amount and quality of the teaching given to undergraduates, and three or more years of special training is being offered to interns, assistant residents and residents. Therefore, while all recent medical graduates have a much better fundamental understanding of all the specialties than the graduates of former years, and while the younger general practitioners and those in specialties of a general character, such as internal medicine, are qualified to care for many pediatric problems which were formerly neglected or required the care of a pediatrician, there is the disadvantage that modern medical education, with its great emphasis on specialized training, may cause too early and too narrow specialization.

The increasing turn of physicians toward the specialties is due not only to the increased satisfaction which comes from doing better work within a limited field, the greater honor, the emoluments and the chance to live in the city of one's choice, with perhaps a university appointment, but also to the fact that the graduate of recent years can get desirable hospital appointments, with few exceptions, only in the specialties and is not fitted either psychologically or actually to do general practice. All too often as an undergraduate he specializes as much as possible in order to be more certain

1. Zahorsky, John, St. Louis: Personal communication to the author.

of an appointment in the department of his choice. Should he choose and be appointed to a rotating internship he must spend at least half his time in the department where he hopes to be appointed assistant resident and resident. After finishing this long course of postgraduate training he finds it difficult to get a suitable short term appointment in another department. Or if he goes into general practice for a time he usually cannot return to an appointment in another department, because such posts are filled by men who have remained after graduation to go through the regular succession and too often the head of the department fears that the man who has practiced is too advanced to make sufficiently pliable house officer material.

EDUCATION OF THE PEDIATRICIAN

I think that changes should be made in medical education to broaden the training of the specialist and make it easier for the man who is in general practice to get the best training in the specialty of his choice; and by the best training I mean a hospital appointment rather than a postgraduate course. Every reasonable effort should be made to discourage the undergraduate from becoming prematurely a specialist. This can be done by helping him to realize that the best basis for any specialty is the greatest possible attainment in all fields of medical knowledge. Even more can be accomplished by the assurance that his hospital appointment will depend on the excellence of his work, his showing of sound judgment and above all his manifestation of such attributes of character and personality as will make him one of those best fitted to carry on the highest ideals of medicine, rather than on his exclusive attention to and cultivation of a single department and its teaching staff.

During the hospital years capable house officers should be encouraged to spend at least one year working in one or two departments other than the one in which the following two years will be spent. I can think of no better training for pediatrics than a year spent in the surgical, the orthopedic or, perhaps best of all, the ear, nose and throat service. I am certain that at least six months or, better, an entire year in pediatrics would be of great value to the future patients of any specialist who may care for a considerable number of children. Such an exchange of interns should be made a part of a deliberate plan even though it would entail some administrative difficulties and would demand closer attention to the service by the teaching staff for a time after the exchange. It would also make necessary the amendment of the by-laws of some academies and colleges to remove the condition that time must be spent in preparation for the practice of a specialty and to substitute evidence of fitness and accomplishment as the major requirement for admission and certification. This change would be following the recommendation of many leaders in education, who are advocating comprehensive tests of accomplishment without regard to time spent in preparation as the basis for degrees and other honors. Such a program would be of especial and peculiar benefit to the young pediatrician, and automatically it would enable young practitioners to live and work in urban communities, where a too rigid limitation of practice would prevent them from making a decent income.

Opportunity for physicians who have spent a few years in general practice to return to hospital positions rather than to the lesser benefits of formal postgraduate courses is, I believe, greatly to be desired, and a

valuable by-product would be the encouragement given to younger graduates to go into general practice for a time and then return for further training.

THE CHALLENGE OF PEDIATRICS

The work of pediatrics has not been completed. It offers an ever increasing challenge, asking its followers to pray not only for more worlds to conquer but for wisdom and energy sufficient to meet the heavy demands placed on them. While the solutions of the older, simpler problems of feeding and regulation of the life of the infant have become fairly common knowledge and are reasonably well practiced, there remain many more numerous and complex problems.

Family life no longer rests on the simple predicates of a father who was the lord and master of the household; a mother who was the family drudge, in whom it was unseemly to complain openly of her lot, even though loss of temper, with satisfaction (the "release" of modern psychiatry) obtained from dealing out swift and summary punishment, caused no criticism or upbraidings of conscience, and children who were "seen but not heard" but were under the constant and beneficent discipline imposed on them by their share in the necessary tasks of everyday family life. The empty water bucket and wood box were powerful disciplinary forces, for which it is difficult to find counterparts in modern life. Pediatricians can do much for parents and children as teachers and interpreters of modern knowledge, not only to make smooth the ways of family life but to make it, as it must always be, the greatest means of fitting the child for the abundant life. He can help the father back into his rightful place in the family circle, from which modern economic life has almost removed him, and he can lead the distracted mother out of the mire of partially understood child psychology, in which she wanders in constant fright of Giant Malnutrition and of Giant Despair, lest some slight fault of hers may hurl her child into the eternal abyss where conditioned reflexes and repressions have their abode.

The new field of the adolescent period (from 12 to 18 or even 20 years) is best approached by the pediatric route. Sound training of parents and children throughout the preadolescent years will reduce the difficulties of this period to a minimum, and the pediatrician who gives of himself to the care of children from babyhood onward literally grows into an understanding of these problems and a sympathy for the "big children" which can be gained in no other way.

A sound working knowledge of endocrinology must have a considerable place in pediatric practice. With due respect to the limitations of the present state of knowledge and its practical applications to growth and development, I feel that this field of therapy may well usher in a new era of human welfare.

Pediatric training is an excellent foundation for the study of any branch of medical knowledge which may be the lifelong interest of the student. For example, surgery has its special applications during childhood, while the study of body mechanics during normal growth and development in individual patients will add much to the clarification and practical application of this very important branch of child welfare. Allergic hypersensitiveness is sufficiently different in its manifestations during childhood and during adult life to justify the giving by some of its students of especial attention to the problems peculiar to the earlier years of life. Or one's interest and abilities may lead one

to study the central nervous system intensively. Such a study will not only be absorbingly interesting but will be most valuable if practice is carried on in communities which are not well supplied with neurologic skill and knowledge. A knowledge of the ear, nose and throat will enable the pediatrician to treat infections of the respiratory tract at least as well as and I think better than any other practitioner. The contagious diseases, with their complications, will yield results in both curative and preventive medicine to any one who plows deeply in this field instead of merely harrowing, as is still too often done. The pediatrician is especially fitted to deal with the public health aspects of medical care for children. This activity will be of especial importance in rural communities, where, as I have said before, good pediatric care is badly needed; but there is a great need for pediatric guidance in the larger centers also.

THE TREATMENT OF ADDISON'S DISEASE

EDWARD H. RYNEARSON, M.D.

ROCHESTER, MINN.

Time will not allow detailed discussion of the historical background, etiology or pathology of Addison's disease. This can be found in the monograph by Rowntree and Snell.¹ This paper will therefore be limited to a consideration of the essential points of treatment.

Briefly the principles behind the management of patients with Addison's disease are as follows: In the first place, these patients are suffering from a destruction of the adrenal cortex. Earlier reports, such as that by Barker,² showed a high incidence of tuberculous destruction. Recent reports reveal an increasing incidence of simple atrophy of the cortex, but it will require more time to determine whether this change in incidence is more apparent than real. Guttman³ found that the duration of the disease was longer when primary atrophy of the cortex was present (34.02 ± 4.40 months) than when the cortex was destroyed by tuberculosis (13.15 ± 2.54 months). If there is tuberculous destruction of the adrenal cortex, then, in a high percentage of cases, tuberculosis is present in other parts of the body. It sometimes happens that the attending physician can effectively correct the deficiencies caused by Addison's disease and yet the patient dies of renal, osseous, pulmonary or peritoneal tuberculosis. If the patient with Addison's disease does have tuberculosis, he must receive special care for this condition. If the patient has active pulmonary tuberculosis, the prognosis is very bad.

In the second place, regardless of the cause of the destruction of the cortex, there follows a lack of adrenal cortical hormone or hormones. Detailed biochemical and physiological studies of these substances may be

found in the published reports of Hartman,⁴ Kendall,⁵ Grollman,⁶ Zwemer⁷ and Swingle.⁸ Here only the fact need be mentioned that the cortical hormone or hormones are essential to life and that they have at least one important function, the control of the blood electrolytes. I will not discuss other functions except to say that there is evidence to suggest that the adrenal cortex plays a prominent role in carbohydrate metabolism.

Thirdly, since patients with Addison's disease lack this cortical hormone, they show changes in the blood electrolytes, namely a loss of chloride and sodium from the body with a retention of potassium, an increase in urea, a marked loss of fluids (with resultant hemoconcentration) and sometimes a marked hypoglycemia. These changes are incompletely understood.

Efforts to correct the disturbances of Addison's disease have proceeded along three lines: The first type of treatment consists in the addition of sodium, in the form of sodium chloride, and either sodium citrate or sodium bicarbonate. Loeb⁹ deserves great credit for his emphasis on the importance of administering large amounts of salt. The second type of treatment consists in the restriction of potassium in the diet; this is described in detail in an article by Wilder, Kendall, Snell and their associates.¹⁰ A third type consists of treatment with an active extract of the adrenal cortex.

Treatment by these three methods or by a combination of them has aroused much controversy. Some believe that all patients with Addison's disease can be treated successfully by the use of sodium salts alone and that the use of a low potassium diet and cortical hormone is not necessary. Others believe that if patients receive enough hormone they need pay little attention to their diet and do not need to take large amounts of sodium salts.

Thompson¹¹ has made some interesting observations. He says:

We have followed three patients with marked Addison's disease, on a normal diet and with no other form of therapy except 10 to 20 cc. daily of Wilson's adrenal cortex extract, for a period of several months to over two years. This, of course, was after they had been brought out of crisis by other additional treatment. With the extract alone, it has been possible to get them to gain large amounts of weight and in general to carry on their normal activity, provided no active tuberculous infection is present. Although some reduction in pigmentation has occurred, it has not disappeared completely, leading us to believe that the extract, at least in the doses we have administered, does not represent complete replacement therapy.

The present paper is not given in the hope of settling this controversy but rather for the purpose of reviewing what may be considered to be adequate methods of therapy. I shall discuss the treatment of Addison's disease by means of the presentation of hypothetical case

histories recorded, for purposes of emphasis, in an informal manner. For the sake of uniformity I will assume that all the patients are men. Actually, of course, the disease more frequently affects women (1.6 to 1).

THE PATIENT IN A CRISIS OF ADDISON'S DISEASE

A patient is admitted to the hospital on a hot afternoon in July in a crisis of Addison's disease. He is too ill to be bothered with an exhaustive quizzing and is put to bed. The room is made as quiet and restful as possible. Any conversation regarding his case is carried on outside the room, for there is no illness more acute than this. During a brief wait for the necessary supplies for treatment the patient's wife, we'll say, tells the essential points of the history. Her husband had been well until three months previously, when he began to complain of loss of weight and strength. His appetite had "fallen off" and he had developed a real "craving" for salt. There had been some nausea and troublesome spells of hiccuping. She had noticed that his skin had changed in color; it was darker, and yes, come to think of it, she had noticed the appearance of many freckles which looked like india ink. In the last few days "since it got so hot" he had become much weaker and hadn't been able to go to work. Today he had vomited every-

TABLE 1.—The Blood in the Crisis of Addison's Disease (Hypothetic Case)

	Mg. per 100 Cc.				
	Normal Values	First Day	Second Day	Third Day	Fifth Day
Urea.....	10-40	120	80	60	40
Chlorides.....	570-620	440	480	520	560
Sodium.....	315-330	260	270	290	320
Potassium.....	16-22	26	24	23	20

thing she had given him and had had a troublesome diarrhea. He had then complained of severe epigastric pains and finally had "just collapsed" and they had brought him to the hospital.

The physician returns to the room. He examines the patient to determine two things: how low his blood pressure is and how dehydrated he is. The physician does not test the eye reflexes, he does not attempt to palpate the liver, kidneys and spleen, and he does not make a rectal examination. Furthermore he sees to it that the nurses forget the routine for admitting new patients; there is no bath, no rolling the patient around, no enthusiastic administration of an enema (patients suffering from Addison's disease also are made worse by purging). The attending nurses therefore enter into the conspiracy for kindly quiet.

The treatment tray has now arrived. It contains supplies for the collection of specimens of blood and for the intravenous administration of fluids. A needle is placed in the vein and enough blood is withdrawn for the determination of its content of sugar, urea and chloride. Blood may also be taken for analysis of sodium and potassium, although this is not urgent. Without withdrawal of the needle, the administration of a solution composed of 10 per cent dextrose, 1 per cent sodium chloride and 0.5 per cent sodium citrate is begun. To the solution is added 30 cc. of adrenal cortex extract. The patient is made comfortable and quiet again reigns.

But let us say that it is Sunday afternoon and the laboratory technician can't be reached immediately. It makes little difference. There is probably no other con-

dition in which examination of the patient and his blood is so unimportant and in which prompt and energetic treatment is so all important. Regardless of what the laboratory tests show, immediate treatment is the same. The reason for ascertaining the sugar content of the blood is that sometimes there is an acute hypoglycemia and large amounts of sugar are urgently needed. Dextrose should always be accompanied by salt. Allers, Nilson and Kendall¹² have shown that when dextrose alone is injected into adrenalectomized animals the initial hyperglycemia may be followed by a fatal hypoglycemia. The determination of the amount of urea and chlorides in the blood gives the physician a basis for judging subsequent improvement and guiding subsequent treatment. There are tests other than those of the sugar, urea and chloride content which are of considerable interest to students of this disease. Such tests are for blood volume and the amount of sodium and potassium in the blood. These tests, however, are beyond the reach of many physicians and laboratories. The patient I am now considering is found to have the usual changes in the chemical constituents of the blood (table 1).

Within an hour or so the patient is then found to have improved. His blood pressure has risen from 70 systolic and 50 diastolic to 86 systolic and 60 diastolic (the blood pressure often rises slowly and may never reach normal). The epigastric pains are less and he is much more responsive. He asks for a drink and is given fluids ad libitum. The intravenous administration of fluid is continued during the night and another 20 cc. of adrenal cortex extract is added to the solution. By morning he may have received 3 or 4 liters of this solution and 50 cc. of the extract. The value for blood urea has dropped to 80 mg. per hundred cubic centimeters and the plasma chlorides have risen to 480 mg. The patient is feeling infinitely better and the needle is taken from his vein. Now he may be bathed and given general nursing care, but only those things necessary for his comfort are allowed. He is now given "Addison's elixir"¹³ to drink.

In the afternoon the patient again feels weak and 2,000 cc. of the solution is again given intravenously together with 20 cc. of adrenal cortex extract. No one can foretell how long it will be necessary to keep up this "emergency treatment." (Snell and Morlock¹⁴ reported one case in which 255 cc. of adrenal cortex extract was required in nine days, during which time the patient received more than 20 liters of fluid intravenously; at the end of this period recovery from the crisis was complete.) In a few days the patient feels much improved and treatment is instituted which is similar to that to be described for the patient with chronic Addison's disease.

No single case, of course, can illustrate all the features of Addison's disease. For example, the crisis did not occur in this case until the patient had had symptoms for several months. In some cases a patient's crisis may be the first indication of his illness. Furthermore, while this patient's crisis responded rapidly to treatment, another patient might have been seriously ill for

12. Allers, W. D.; Nilson, N. W., and Kendall, E. C.: Studies on Adrenalectomized Dogs: The Toxic Action of Potassium. *Proc. Staff Meet., Mayo Clin.* 11: 283-288 (April 29) 1936.

13. To 1 liter of water 10 Gm. of salt and 5 Gm. of sodium citrate are added. This is flavored to taste with fruit-flavoring extracts (such as those of the Calumet Tea and Coffee Company, Chicago) and is kept well iced. The patient should drink at least 1 liter of this each day.

14. Snell, A. M., and Morlock, C. G.: Neurologic Symptoms Produced by Suprarenal Insufficiency: Report of a Case. *Proc. Staff Meet., Mayo Clin.* 11: 551-554 (Aug. 26) 1936.

a week or more. On the other hand, the patient's symptoms may be quite different from those recorded in this case. In this case the gastrointestinal symptoms were prominent. In Snell and Morlock's case, which has been previously referred to, there were so many symptoms related to the nervous system that an associated tuberculous meningitis was suspected. In still other cases the patient's symptoms may be largely associated with circulatory collapse. Each case is therefore different and requires individualized treatment.

Many deaths from the crisis of Addison's disease are due to delayed recognition of the condition or to a delay in treatment. Treatment must be both prompt and energetic. The importance of administering large amounts of sodium chloride cannot be overemphasized. During the crisis some patients may lose as much as 10 pounds (4.5 Kg.) in two days; this loss of weight is largely a loss of fluid, and fluids and sodium salts must be replaced.

THE PATIENT WITH ADDISON'S DISEASE WHO REQUIRES AN OPERATION

Surgery of even the simplest type was until recently denied patients suffering from Addison's disease. The extraction of a tooth was formerly sufficient to cause death. Fortunately this state of affairs no longer exists, and it is now possible to perform necessary operations, although, of course, there is an increased risk.

Briefly, let us say that this patient presents the typical appearance of Addison's disease but in addition is suffering from tuberculous destruction of the left kidney. It is considered advisable to remove this kidney. The patient knows that without this operation his outlook is very dark and he agrees to accept the chance which operation offers. The preoperative preparation requires at least a week and consists in placing him on a regimen which includes the low potassium diet (to be described later), the daily oral administration of a quart of "Addison's elixir" and the daily intramuscular or subcutaneous injection of 10 cc. of adrenal cortex extract. On the morning of the operation the patient receives by intravenous injection 2 liters of a solution of 10 per cent dextrose, 1 per cent salt and 0.5 per cent sodium citrate with 20 cc. of the extract. This procedure is repeated after the operation. The length of time that intravenous treatment and careful observation are necessary depends on the patient's condition and it may vary from several days to several weeks. On this regimen the patient makes a very satisfactory recovery. He owes his life to the close cooperation between surgeon and physician and to the energetic application of the measures just mentioned. Precision is demanded; there must be nothing slipshod in the treatment of such a patient as this.

Many patients who require operation for the destructive lesions of chronic tuberculosis suffer from a postoperative reaction which may be described as a "severe tuberculin reaction." This does not occur more frequently among patients suffering from Addison's disease, but it is more dangerous in association with this disease. The accompanying chart (of an actual case) demonstrates both the severe reaction, the temperature going to 105 F., and the energetic treatment which was required for more than two weeks' time.

Patients with Addison's disease are also extremely sensitive to certain types of medication. A very small amount of insulin or thyroid extract may kill a patient with Addison's disease.

THE PATIENT WITH CHRONIC ADDISON'S DISEASE

This patient's skin is typically pigmented and he has experienced some of the other symptoms of the first patient who was admitted in crisis, but in a milder form. This is his third admission, and he enters the hospital under his own power.

He was first seen, we will say, in the spring of 1935, when the diagnosis of Addison's disease was made. He did not have a particularly severe form of the disease and it was not believed necessary to administer adrenal cortex extract. Ten Gm. of salt and 5 Gm. of sodium citrate were prescribed, to be taken daily by mouth. This was first given in the form of enteric-coated tablets, but when the patient did not improve, his stools were passed through a sieve and the tablets were recovered unchanged. This amount of salt and sodium citrate nauseated him when swallowed in capsules. "Addison's elixir" proved very satisfactory. Examination of the patient's lungs disclosed the presence of pulmonary tuberculosis, but there was no evidence of activity.

The patient's second admission was during the summer of 1937. He had enjoyed improved health since his first admission. When a bad cold developed he had become quite weak, but he had drunk 2 quarts

Addison's disease and chronic tuberculosis, showing severe postoperative reaction.

of the "Addison's elixir" each day instead of one and had made a rapid recovery. The reason he gave for returning at this time was "this hot weather has got me down and the salt won't pull me up."

Since the time of this patient's first admission it had been observed that potassium is very toxic to patients with Addison's disease. It was believed that the reason for the patient's continued difficulty was the fact that his food contained too much potassium. Sister Victor¹⁵ was therefore asked to plan a diet which contained only small amounts of potassium. The suggestions and diet were as follows:

A PLAN FOR A DIET LOW IN CONTENT OF POTASSIUM

In arranging a diet restricted in potassium, it is necessary (1) to limit the selection of bread, cereal and sugars to the highly refined products, (2) to restrict moderately the use of milk, meat, fruits, vegetables, condiments and certain beverages, and (3) pending further investigation to cook meat and vegetables according to a special method whereby the content of potassium is reduced.

The special method suggested for the cooking of vegetables consists in cutting the vegetable into small pieces and cooking them in from six to eight times as much water as vegetable. Cooked according to this

15. Victor, Sister Mary: Diets Low in Content of Potassium (unpublished data).

method, the potassium is reduced from 60 to 70 per cent without a concurrent diminution of palatability. The special method suggested for the cooking of meat consists in cutting the meat into small pieces and cooking it in a so-called parchment paper bag in from six to eight times as much water as meat. By this method the content of potassium is reduced to a fourth of the original level while other nutrients and extractives which give flavor are retained in the meat.

Foods to be strictly avoided because of their high content of potassium include soups, broths and gravies containing meat stock or meat extracts, catsup, chili sauce, mustard and other meat sauces and seasonings, dried fruit and vegetables, bran, molasses, Postum and chocolate.

A plan for an adequate diet in which the content of potassium does not exceed 2 Gm. is given in table 2.

TABLE 2.—Adequate Diet in Which Potassium Does Not Exceed 2 Gm.

	Gm.	Approximate Measure
For breakfast:		
Orange or grapefruit.....	100	1 average-sized serving
Cream of wheat.....	15	1 average-sized serving
Egg.....	50	1
Bacon.....	10	2 small strips
Bread, white (may be toasted).....	30	1 slice
Butter.....	10	1 square
Cream.....	30	½ cupful (scant)
For second meal:		
Meat, specially cooked.....	75	1 fairly large serving
Potato, specially cooked.....	100	1 serving
Raw vegetable (lettuce, celery, tomato, cabbage, Swiss chard or watercress)....	100	1 serving
Mayonnaise.....	15	1 tablespoonful
Bread, white.....	30	1 slice
Butter.....	20	2 squares
Fruit (apples, pears, strawberries or tangerines).....	100	1 serving
Cream.....	30	2 tablespoonfuls
Milk.....	200	1 glass
Cheese.....	20	1 cubic inch
For third meal:		
	50	1
	25	1 serving (½ cup)
Carrots, onions, turnips or squash)....	100	1 serving
Bread, white.....	30	1 slice
Butter.....	20	2 squares
Fruit (apples, pears, strawberries or tangerines).....	100	1 serving
Cream.....	30	2 tablespoonfuls
Milk.....	100	½ glass

Further details regarding this diet will be found in an article to be published by Sister Victor.

Lists of permitted substitutions and more detailed directions for the special cooking of meat and vegetables are given in a paper to be published in the *Journal of the American Dietetic Association*.

All foods should be weighed or carefully measured. One cup of weak coffee and two cups of weak tea are allowed daily. Salt may be used in generous amounts, particularly in seasoning the specially cooked foods. Pepper and vinegar are allowed in moderation. White sugar may be used liberally in beverages, on cereal and on fruits. Gelatin, either plain or flavored, may be used in salads or desserts. Carbonated beverages, such as ginger ale and coca-cola, as well as fruits prepared from synthetic beverage powders or crystals, may also be taken as desired. Any one of these beverages may be used as a carrier for the "extra" salt usually prescribed.

By using this plan as a basis and by making appropriate substitutions for the foods listed, many varied and attractive menus can be planned.

The patient improved rapidly and was dismissed, with the advice to follow the "low potassium diet" and

to continue to take at least 1 quart of "Addison's elixir" each day; this was to be taken during periods of stress such as are caused by hot weather and intercurrent infections.

On his third admission (say in May 1938) the patient reports that he has been much stronger since he has followed the regimen of "salt, citrate and low potassium diet" than when he simply took salt and citrate and ate a general diet. However, he says that he has not felt well lately and that he has returned for any additional suggestions for improving his health.

The only additional suggestion which can be given at this time is that he should be given adrenal cortex extract. This is likely to be more necessary when pulmonary tuberculosis is present. How much the patient should take will have to be determined by clinical trial in much the same manner as one determines the dosage of insulin for a diabetic patient.

The patient is found to respond satisfactorily to the subcutaneous or intramuscular injection of 5 cc. of extract every day. He is taught the technic of self administration, and by adding 0.5 cc. of 1 per cent procaine to the solution he suffers no discomfort. It may be possible for him to omit the injections on occasions, as, for instance, during the cooler months; it may also be necessary to increase the amount on other occasions, particularly during hot weather and in other periods of stress.

In discussing this case it may be said that the patient's first period of treatment with salt and sodium citrate alone was good; that the second period of his treatment with the valuable addition to the first regimen of a low potassium diet was better; that for this patient the addition of adrenal cortex extract to his previous regimen was additionally beneficial, and constituted, for this particular patient, the best treatment. There have been few patients who have not reported better health when, in addition to controlling the potassium content of the diet and securing adequate chloride and sodium, some adrenal cortex extract was taken. This applies especially to patients who have systemic tuberculosis.

THE PATIENT SUSPECTED OF HAVING ADDISON'S DISEASE

Patients may be suspected of having Addison's disease because of unusual pigmentation, hypotension or weakness—or be just "suspected" of having it. The patient I shall consider now is 18 years old. He is deeply pigmented, but he has just spent the summer as a counselor at a boys' camp and is so sunburned that his color is of no significance; he does not have any "india ink" freckles. He has entered the hospital because he felt quite weak toward the close of the camp period; the camp physician found his blood pressure to be low and the question of Addison's disease was raised. A period of two weeks has elapsed and he is already feeling much improved; however, his parents want the diagnosis proved or disproved. Nothing is found on physical examination or on study of the blood electrolytes to substantiate the diagnosis of Addison's disease. However, it is well known that this is not conclusive, and it is decided to carry out a "provocative test."

Provocative tests should be performed only in the hospital and only when facilities are adequate for immediate treatment if the patient does have Addison's disease and a crisis is induced by the test. Earlier tests, such as the one originally suggested by Harrop and his

co-workers,¹⁶ had as their basis the fact that if Addison's disease was present the patient would be made worse by the withdrawal of salt from the diet and there would be positive changes in the blood electrolytes. However, some patients with unquestioned Addison's disease were found to withstand withdrawal of salt for appreciable periods. In later tests potassium was added to the diet; this accelerated the response if Addison's disease was present and greatly increased the reliability of the procedure. All these tests, however, required that the patient be made worse if the test was to be considered positive—and sometimes the patients were made very much worse. The risk of such a test, therefore, was not insignificant.

The patient I am considering is given the test outlined by Cutler, Power and Wilder¹⁷ and this test will not be described in detail here. It has as its basis the determination of the concentration of chloride in the urine at the end of a brief (fifty-two hour) period of a standard "high potassium-low salt" regimen. This test is the simplest and, in experienced hands, the safest yet described. The results indicate that the patient does not have Addison's disease. He is therefore told that there is no evidence for the diagnosis of Addison's disease. He is also told that, while the test has given every indication of being very reliable, no test is 100 per cent accurate. He is dismissed with the reassurance that his symptoms probably were the result of overwork beneath a hot sun, with an insufficient intake of salt. We insist, however, that he cooperate with his local physician for future observation.

RESULTS OF TREATMENT

It is difficult to evaluate the results of treatment of Addison's disease. There are at least three factors which militate against acceptance of "survival time" as a criterion for conclusions: (1) Some patients have survived for years without treatment of any kind, one patient in a case reported by Snell¹⁸ having lived for seventeen years without the advantage of "modern" treatment; (2) "modern" treatment has been available for clinical trial for an insufficient period of time, and (3) there are too many "variables," such as the different types of extract used and the varying degrees of cooperation between physicians and patients, to permit statistical comparison of different groups of cases as treated in different parts of the country.

Greene¹⁹ appreciated these difficulties in collecting material for his recent excellent and thorough study, in which he reviewed his personal experience in thirty-four cases of Addison's disease. This had begun when he and Rowntree, with Snell, were studying these cases at the Mayo Clinic. Greene compared this group of thirty-four treated patients with 266 untreated ones and concluded: "The treatment added little to the apparent life expectancy in many cases but definitely prolonged life in a limited group of cases. The duration of the disease was more prolonged in this series of cases than has been reported with earlier methods of treatment."

Hausner, Snell and I²⁰ have recently compared the results of treatment in two groups of cases seen at the clinic. The first group of forty-six patients was seen between May 1, 1930, and Oct. 1, 1933. Adrenal cortex extract was introduced at the beginning of this period and treatment with sodium chloride in the middle of it. The second group, of forty-three patients, was seen between Oct. 1, 1933, and July 1, 1937. The use of sodium bicarbonate or sodium citrate was introduced early in this period and after May 1935 the low potassium diet was used. These two groups are more suitable for comparison than would be true of patients treated in different localities. The deaths at the end of the period that ended Oct. 1, 1933, numbered thirty (65 per cent); the deaths at the end of the period that ended July 1, 1937, numbered seventeen (40 per cent).

Of the seventeen patients in the second series who died, six were women, not one of whom was given the low potassium diet. Of the eleven men who died, only four were given what might now be termed "adequate" treatment. Perhaps a better idea of the efficacy of the newer type of treatment can be obtained from the knowledge that from Oct. 1, 1933, to Oct. 1, 1934, eight deaths occurred in seventeen admissions, whereas from July 1, 1936, to July 1, 1937, there were only three deaths in fourteen admissions, two of them in cases in which extensive tuberculosis had caused marked destruction of the vertebrae. Thus from a very brief analysis of these crude mortality statistics it is seen that definite improvement has followed the application of what might be termed the "latest" type of treatment.

Far more important than this type of analysis, however, is the knowledge which has been gained from observations that do not lend themselves to statistical study. By this I refer to the fact that all of us who have been treating Addison's disease for many years have noticed that, with our present method of treatment, most of our patients are feeling better than they ever did with previous types of treatment. Many are able to follow gainful occupations and to resume their place in society. One of our patients, a young woman who was rescued from a crisis which in former years would have resulted in her death, is now teaching school every day and is feeling quite well. Another young man is working every day and is the proud father of a son, the first patient with Addison's disease, of whom we have knowledge, who has become a father. We have no record of a woman with Addison's disease having had a child, but Kendall¹² has reported the successful delivery of healthy pups in the case of an adrenalectomized dog that had been maintained with sodium chloride and sodium citrate without adrenal cortex extract for months before and during gestation. Furthermore, patients with Addison's disease can, with this treatment, survive stresses which formerly would have caused their death. They no longer die in large numbers during the first hot spell of the summer. They now are able to have necessary surgical operations and can withstand minor intercurrent infections.

Patients with Addison's disease will continue to die from tuberculosis; until we learn more, others will die from causes which we do not understand. These deaths are unfortunate, of course, and serve as a challenge for future study. But there are many other deaths which

are most regrettable because they could have been prevented if only knowledge which is already available had been utilized. Many of these deaths are due to negligence on the part of the patient. The patient must be taught that his safety depends on being just as vigilant as any patient with severe diabetes, or more so; he must follow his diet as closely, in order to avoid a dangerous intake of potassium, and take his sodium salts and extract just as religiously as the diabetic patient follows his diet and takes his insulin. He must avoid stresses and strains such as intercurrent infections and hot weather even more carefully and he must cooperate with his physician most faithfully.

Other deaths which could be prevented are those which follow the delayed recognition or incomplete treatment of an acute crisis. Again this emergency can be compared to the emergency of diabetic coma. The patient with Addison's disease must learn the warning signs of impending trouble and he must hasten to his physician, who must be prepared to treat him promptly and energetically. Not all patients in the crisis of Addison's disease can be saved, but most of them can.

Finally it should be stated, as mentioned previously, that there are some patients with Addison's disease who die in spite of energetic treatment, which includes all the suggestions mentioned here. They die in spite of the fact that chemical analysis of the blood indicates the return to normal values of the electrolytes. We do not know why they die. This is but one of the many unsolved problems concerned with Addison's disease.

No attempt has been made in this paper to create the impression that a cure for Addison's disease is being announced. Far from it. Progress is being reported, however, and it is believed that the best available treatment should consist in (1) the restriction of potassium in the diet, (2) the addition of sodium salts to the diet, (3) the use of an active extract of the adrenal cortex when it is needed, (4) the training of the physician and the patient in the details of treatment of the chronic state of the disease, and (5) the early recognition of acute remissions and their energetic treatment.

ABSTRACT OF DISCUSSION

DR. HERBERT M. EVANS, Berkeley, Calif.: Dr. Ryneerson's report is particularly valuable to the profession because the malady is so rare that only a clinic like that at Rochester would have the opportunity of treating any considerable number of cases. It was at that clinic that the first conclusive evidence of the value of substitution therapy in the classic efforts of Rowntree and Snell with the extracts of a decade ago was shown. In addition to the advances as to the group of substances which may be designated as adrenal cortex principles, in which Kendall has had a significant part, equal attention has been paid the newer knowledge of the sodium-potassium metabolism in these patients. Recently, by the use of a new tool, Dr. Anderson of our laboratory, in conjunction with Lawrence, has confirmed the observations of Loeb, Harrop and others that adrenal subnormality involves the increased secretion of sodium and retention of potassium, the new tool being the use of tagged atoms of sodium potassium, those on which radioactive properties have been imposed by the cyclotron. In conditions of subnormality or destruction of the adrenal cortex, it is natural to look for subnormality in each of the known functions of the adrenal cortex. But for the present one can, perhaps, dismiss the capacity of this tissue to secrete estrogens and androgens or some substances related to the sterols of the sex hormone group. There appears to be no question that the primary object of concern here is the adrenal secretion of the vitally necessary substance which regulates the metabolism of

the electrolytes. From the recent studies of Long and others it is known that the same hormone plays an important role in the metabolism of carbohydrates. One of the most debated questions is whether the mediation of the pituitary in carbohydrate metabolism is to be explained solely by its control of this function of the adrenal cortex. That the anterior pituitary substance called the adrenotropic hormone definitely increases the production of this principle by the adrenal cortex has, I feel, been demonstrated in cooperative experiments between our laboratory and that of the Mayo Foundation. If the position taken by Long in his debate with Houssay of Buenos Aires is correct, it should be possible to produce permanent diabetes by overconveyal of this hormone to normal animals as we were able to do with anterior pituitary extracts some years ago in Berkeley, and as has been recently more particularly studied by Young of London. This has not yet been accomplished, but it may be achieved in the near future.

DR. LESTER J. PALMER, Seattle: We have just heard a masterly summary of present knowledge of Addison's disease. I believe that the group of measures advocated—administration of salt and extract plus restriction of potassium—deserve endorsement and trial. This belief is based on the fact that the recommended regimen includes all the therapeutic agents indicated by our present knowledge. At the Mayo Clinic only eighty-nine cases have been observed in eighty-six months, or about one new case a month. In Seattle, in eight hospitals representing a capacity of 1,800 beds, where diagnoses have been indexed for periods varying from five to seventeen years, a diagnosis of Addison's disease has been recorded only twenty-six times. The bureau of vital statistics for the state of Washington (population 1,700,000) shows that for the five year period 1933-1937 Addison's disease appeared as a primary or contributory cause of death only twenty-five times. I believe these figures are really higher than the true figures would be. It should be mentioned that there is duplication of cases in the various series. At least two of the Seattle cases are known to be included in the Mayo Clinic group. Is this low incidence of Addison's disease apparent or real? Are patients dying in acute crises of Addison's disease, either as medical deaths or following surgical procedure, without being recognized? There is available the method of subjecting the suspected patient to test conditions outlined by Cutler, Powell and Wilder, which is apparently a safer procedure than that previously employed. May it not be possible that earlier diagnoses will become a fact and that a not inconsiderable number of patients who would previously have died in unexplained circulatory collapse will now be recognized as having Addison's disease?

DR. W. O. THOMPSON, Chicago: I should like to emphasize what Dr. Ryneerson has said about the treatment of a crisis, which in Addison's disease presents an emergency fully as great as if not greater than that presented by diabetic coma. When a crisis has advanced to the point of unconsciousness, it is usually impossible to revive the patient with any form of therapy. I should like to stress the importance of large doses of adrenal cortex extract as well as of sodium salts in the treatment of a crisis in Addison's disease. I have used as much as 150 cc. of adrenal cortex extract in the course of the first twenty-four hours, a much larger dose, of course, than is required later for maintenance. Dr. Ryneerson has already told you that at the Mayo Clinic they administer as much as 60 cc. of extract in the course of the first hour or two and then give an additional 30 or 40 cc. Early in a crisis a patient may be revived by the use of 40 or 50 cc. of extract alone, but if a crisis is well advanced it is necessary to add sodium salts, because the reserve of sodium in the body is depleted.

DR. EDWARD H. RYNEARSON, Rochester, Minn.: All of us are grateful to Dr. Evans for his remarks. The greatest advances in the treatment of Addison's disease have come from the laboratories and I am hopeful that work now in progress in Dr. Evans's laboratory may help further. Many patients suffering from either overfunction or underfunction of various endocrine glands enjoy periods of spontaneously improved health. Dr. Palmer referred to an interesting patient. If we can accept the diagnosis of Addison's disease as accurate, then we should be able to prophesy that with his present careless

attitude he is riding for a fall. If I were asked to guess the explanation for this patient's improvement, I should say that he probably has had some regeneration of the adrenal cortex. This is not unknown. Dr. Thompson's discussion is appreciated because of the fine work he has done in the study of this disease, which has just been reported before the the Association for the Study of Internal Secretions.

ANATOMIC FACTORS IN PATHOGENESIS AND TREATMENT OF URETHRO- CELE AND CYSTOCELE

ARTHUR H. CURTIS, M.D.

BARRY J. ANSON, PH.D.

AND

CHESTER B. McVAY, M.D.

CHICAGO

The levator ani muscles and their fascia have been generally conceded to be the essential supports of the urinary bladder.

Cystocele has been recognized to be a true hernia of the bladder—more specifically, a herniation of the fundus and trigon, which are those parts in association with the anterior vaginal wall.

The degree of incontinence of urine is evidently dependent on whether there is a urethrocele, which may or may not be associated with a cystocele, and varies enormously in different cases. It has been generally accepted that the specific anatomic lesion responsible for the incontinence is relaxation of "the sphincter muscle," yet most physicians have had a rather vague picture of the sphincteric anatomy and a very meager knowledge of the physiologic mechanism of vesical control.

The modern conception of correction of a cysto-urethrocele with incontinence has been that of repair of a hernia, with reenforcement of the urethral and trigonal support; but the anatomy of the structures used in the support of the mobilized and replaced and more or less incontinent bladder and urethra has not been well understood.

I believe that we have found answers to the major queries which arise in relation to these problems. The answers were inadequate after a concerted attack from the combined points of view of the anatomist and the gynecologist, despite painstaking expert dissection of the pelvis of five selected female bodies; it was only after a sixth dissection was made, this time from within the pelvis in the case of a remarkably favorable specimen, that the anatomic relationships were revealed clearly and unmistakably.¹ The accompanying illustration is Tom Jones's depiction of the anatomy of cysto-urethrocele as viewed from the vaginal aspect at operation.

ANATOMY

Let us view the dissected pelvis from within, with the viscera, the parietal peritoneum and the pelvic cellular tissue removed, only the lower part of the bladder, much of the vagina, and the terminal portion of the rectum remaining: The endopelvic fascia is readily recognized, without effort, as the reflection upward on the viscera of the firm fascial layer covering the pelvic

floor. An aponeuroticofascial ridge sweeps forward from the region of the spine of the ischium and soon divides into an inferior fascial arch, the white line, and the somewhat more superiorly placed, slightly curved arcuate ligament.

The dissection, if skilfully performed, reveals firm fascia ensheathing the bladder and the vagina, with a more delicate similar envelop for the rectum. The fascial tubes are the endopelvic fascia.

The anterior vesical reflection of the endopelvic fascia, i. e. the pubovesical fascia, creates a vesical sling from the pubis. The portion of the enveloping vesical layer on the vaginal aspect of the bladder is in intimate relation with the musculature of the bladder wall. A similar, less marked relationship is found between the vaginal reflection of fascia and the musculature of the vaginal wall. Thus there is a double layer of fascia between the bladder and the vagina, and each receives some muscle fibers from the wall of its adjacent viscus. The ensheathing fascia surrounding the viscera is firm and adds materially to their support. It begins on each viscus at the bottom of the pelvic cavity, and therefore the lowermost vagina and the lowermost urethra are not enveloped by the endopelvic fascia.

On removal of the fascia which lines the pelvic floor and its visceral reflections (the endopelvic fascia) and on excision of the viscera to a lower level, the levatores ani and coccygei, originating from the posterior aspect of the superior pubic ramus, the arcuate ligament (not the white line) and the spine of the ischium are seen to pass mediad and backward bilaterally, chiefly antero-posteriorly, toward the anococcygeal raphe and the sacrum. As the levatores ani sweep past the viscera, broad straplike bands of fibers are inserted into the lateral aspects of the rectum and the vagina, furnishing firm supports; an almost negligible number of strands are inserted into the posterolateral aspects of the urethra.

With the bladder excised down to the vesical neck, the urethra is seen as a thick walled shaggy tube, 1 cm. or more in diameter, its wall comprised of intrinsic muscle fibers which constitute the internal sphincter, naturally in a state of tonic contraction and in control of the normal accumulation of urine. One now sees the uterosacral ligament-like portions of the urogenital diaphragm arising from the pubis and firmly inserted into the lateral aspects of the urethra.

The urogenital diaphragm, or triangular ligament, at a lower level and anterior to the pelvic diaphragm, completes the pelvic support. With the urethra and the right half of the vagina excised to a still lower level and the levator ani and fascia removed from the right side, there is exposed the large ischio-rectal fossa, anterior to which is the broad firm transverse musculo-membranous urogenital diaphragm arising from the inferior rami of the pubis and ischium, stretched across almost the entire anterior half of the pelvic outlet at right angles to the vaginal canal. The muscles of the urogenital diaphragm constitute the external sphincter of the urethra. The muscle fibers of the diaphragm are directed chiefly transversely toward the midline, where they encounter the vagina and the urethra and are inserted firmly into them. As they meet the urethra many fibers are applied to it, inserted lengthwise along its distal portion, difficult to distinguish from the urethral fibers of the internal sphincter. A most prominent portion of these fibers in intimate relation with

Read before the Section on Obstetrics and Gynecology at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

1. Three anatomically accurate illustrations of this dissection in its various stages will accompany another contribution, now in preparation.

the urethra consists of paired bands of the glistening superior fascia and underlying muscle fibers of the diaphragm arising bilaterally from the inferior pubic ramus near the midline and inserted into the anterolateral aspects of the urethra, presenting a miniature counterpart of the uterosacral ligaments. Some of the fibers of the diaphragm reach the midline beneath the urethra, but they form an insignificant layer here, in contrast with the lateral firm portions of the diaphragm.

It is my purpose to avoid discussion of a controversial subject; yet I must mention that microscopic study was made of tissue removed from several patients during operations on cystoceles. Generous blocks of firm supporting tissue excised from various locations during the operative dissections invariably contained much con-

ligaments, which are nothing more nor less than reflections of fascia accompanying the uterine artery and vein.

Childbirth injuries are often comparable with those of an explosion—a generalized stretching, sagging and dragging. With such a lesion it is self evident that all the supporting tissues, far and near, play a part in the pathologic picture.

Uterine prolapse alone may occur with nothing more than stretching of the fascia which lines the pelvic floor, the uterovaginal fascial envelop with its associated muscle fibers and the all important perivascular fascia, known as Mackenrodt's ligaments, which extend, fan shaped, within the folds of the bases of the broad ligaments from the sides of the cervix and uppermost vaginal wall to become attached to the lateral bony walls of the pelvis.

If the lesion is essentially a cystocele or a cysto-urethrocele the disorder is more localized than with uterine prolapse, is lower and more anterior and may spare Mackenrodt's ligaments and the levator ani muscles including their straplike attachments to the lateral aspects of the rectum and the vagina. And, contrary to accepted belief, an extensive cystocele may develop solely as a result of rending and tearing and relaxation of only the pubovesical fascia and the fascial layers between the bladder and the vagina together with the urogenital diaphragm.

In the case of urethrocele alone, stretching of the fascia which ensheathes the intrapelvic urethra and tearing of the urogenital diaphragm away from the pubic bone are the dominant and sometimes the exclusive lesions, with resultant prolapse of the urethra downward and forward.

Pathologic anatomy of cysto-urethrocele as viewed from the vaginal aspect at operation: a, urogenital diaphragm, attenuated beneath the urethra and thick laterally; b, musculofascial vaginal envelop; c, musculofascial vesical envelop.

nective tissue, almost always in preponderance over the muscle fibers; the latter varied in amount according to the individual patient and the region from which the tissue was excised.

PATHOGENESIS OF CYSTO-URETHROCELE

What happens when a major lesion develops, such as a uterine prolapse together with a cystocele?

With the traumatism of childbirth there is a rending of the supporting pelvic tissues, both muscles and fascia, and thenceforth the pelvic viscera sag. The lesion varies according to numerous undiscussed factors involved, such as the size, structure and axis of the bony and ligamentous framework and the size of the fetus, the presentation and the method and rapidity of delivery. Anatomic dissection emphasizes the importance of the fascial supports; a fact borne out by clinical experience when one demonstrates at complete hysterectomy the important supporting power of Mackenrodt's

NERVOUS MECHANISM OF THE BLADDER

The nerve supply and nervous mechanism of the bladder have been worked out fairly satisfactorily, although incompletely:

The sensation of pain travels exclusively through the sympathetic fibers, which pass upward by way of the presacral nerve (the superior hypogastric plexus).

It appears that the mechanism concerned with normal filling and emptying of the bladder resides chiefly in the involuntary muscle of the bladder wall, which includes the circular thickened band of fibers of the vesical neck and urethra, termed the internal sphincter.

The motor nerve supply concerned with this mechanism comes through the paired erigens nerve, otherwise known as the erectile or pelvic nerve, the fibers of which emerge from the spinal cord in the anterior roots of the second, third and fourth sacral nerves and reach the bladder by way of Frankenhäuser's plexus. The afferent impulse to the cord concerned with the normal act of micturition probably travels through the pudendal (pudic) nerve, which reaches the perineum through Alcock's canal and carries afferent fibers to the cord through the second, third and fourth posterior sacral roots. The pudendal nerve also innervates the muscles of the urogenital diaphragm, including the external sphincter of the urethra.

Normally, the internal vesical sphincter is in a state of tonic contraction and controls the accumulation of urine. When the bladder becomes full an impulse to the cord stimulates the erigens (parasympathetic) nerve, with resultant relaxation of the internal sphincter, and at the same time a contraction of the remaining musculature of the bladder wall, thus emptying the bladder.

The external sphincter of the urethra plays no part in the normal control or emptying of the bladder; but it is called into play when the bladder becomes full, and it is all important in supporting the function of the internal sphincter in protecting against sagging and incontinence.

PRINCIPLES OF TECHNIC IN REPAIR OF URETHROCELE AND CYSTO-URETHROCELE

If there is a cysto-urethrocele alone, blunt dissection along fascial planes between the protruding bladder and the vagina and between the bladder and the uterus suffice to mobilize the herniating bladder.

The invariably recognizable musculofascial tissues between the vagina on one side and the bladder and urethra on the other are readily isolated by blunt dissection at operation and consist of the musculofascial components of the urogenital diaphragm below and the ensheathing layers of urethrovaginal and vaginal fascia above, the double layered urethrovaginal fascia strengthened by muscle fibers derived from these viscera.

The freed bladder may be held in replacement by suturing the bluntly dissected musculofascial supports. The union is accomplished by midline interrupted sutures, with more or less attachment to the uterus to accomplish satisfactory closure of the hernial opening. The more thoroughly one dissects the tissues well up over the urethra in the direction of the meatus, with suturing of the thinned-out and retracted musculofascial tissue lateral to the urethra to make a support beneath it, the more one may be assured of control of incontinence; unfortunately there is associated a longer period of time during which the patient will require catheterization.

Other lesions commonly accompany the cystocele. Relaxed Mackenrodt's ligaments may be strengthened by cutting the bases of the broad ligaments and suturing them together anterior to the cervix. For smoothness of workmanship in this detail, it is our custom to make a preliminary denudation of the overlying vaginal mucosa. The supporting pelvic floor should be repaired as a routine.

SUMMARY

Direct etiologic factors in the development of cysto-urethrocele are (1) relaxation of the fascia that lines the floor of the pelvis together with injury of its reflections (the endopelvic fascia), the bladder and the urethra, and the vagina, to the level of the floor of the pelvic cavity; (2) separation of the urogenital diaphragm from its firm attachment to the pubis, or stretching of the diaphragm, which permits the urethra to prolapse downward and forward.

Indirect etiologic factors in the development of cysto-urethrocele include (1) injury of the fascial reflections of endopelvic fascia which ensheath the vagina posteriorly and the rectum, (2) relaxation of the strap-like bands of the levatores ani which firmly support the lateral aspects of the rectum and the vagina, (3) relaxation of more distant supporting structures, including the important Mackenrodt's ligaments and the levatores ani, especially the perineal portions of the latter.

In the controversial field concerned with the relative amount of fascial and muscle tissues present at dissection of a cysto-urethrocele, anatomic and clinical dissections and histologic study of excised pieces of tissue lead to the following deductions: The supporting tissue is predominantly fascia, but there is a generous amount

of associated muscle fibers. Explanation of the derivation of this supporting tissue is as follows: The support in the region of the lower part of the urethra consists of the firm musculofascial tissues of the urogenital diaphragm, a part of which comprise the external sphincter; envelopes of supporting fascia reflected from the fascia of the pelvic floor encase the bladder and upper part of the urethra and vagina, and these, particularly on the vesical aspect, are strengthened by muscle fibers derived from these viscera.

The repair of urethrocele can be best accomplished from the vaginal approach by blunt dissection along lines of musculofascial cleavage, according to the general principles of dissection, with musculofascial support derived from the tissues which have been described, according to the general principles of repair of hernia.

303 East Superior Street.

ABSTRACT OF DISCUSSION

DR. W. T. DANNREUTHER, New York: The authors have clearly outlined the important factors concerned in injuries to the bladder and urethra resulting from birth trauma and indicated the structural principles involved in reparative operations. They have correctly called attention to the fact that a urethrocele is the prototype of a cystocele. The terms "urethrocele" and "prolapse of the urethra" are sometimes erroneously used interchangeably. A urethrocele involves all the walls of the urethra, whereas a prolapse is merely a protrusion of the mucosa through the meatus. This presentation is undoubtedly based on original dissections, which again emphasizes the importance of the endopelvic fascia as a supporting structure. It demonstrates that a cystocele without uterine prolapse may develop despite the integrity of the cardinal ligaments. Urine is normally accumulated in the bladder under a pressure of less than 10 mm. of water and is checked at the vesical orifice partly by the internal sphincter, which is simply a part of the detrusor smooth muscle fibers, and partly by the external sphincter, composed of striated fibers. Only the latter can be contracted voluntarily to prevent micturition when the bladder is full. The physiologic coordination of the detrusor muscle fibers and external sphincter, as well as normal balance of sympathetic and parasympathetic nerve impulses, is responsible for proper bladder control. Dysfunction eventuates in abnormal micturition. I agree with the authors that in doing plastic operations the dissection should be carried well over the urethra and the externally retracted tissues approximated snugly beneath it. In most cases of incontinence, two plicating mattress sutures of Pagenstecher linen, placed in the outer margins of the urethrocele itself, beneath the line of catgut sutures, will be found useful. Fixation of the anterior vaginal wall to the area on the cervix from which the prolapsed bladder has been freed and dislocated upward is prerequisite for the cure of large cystocele.

DR. G. D. ROYSTON, St. Louis: The type of cystocele and urethrocele, interdependent conditions, that I wish to add has to do with this trigonal muscle. This particular injury may be present when no cystocele or urethrocele can be made out from the outside, but can be recognized through a cystoscope aimed at the point where the muscle crosses the internal sphincter. When the patient strains, if this type is present, the floor of the bladder will be seen to go down, but the internal sphincter will not be materially depressed with it. In other words, as a result of the tear of the trigonal muscle near this point, the patient has a functioning cystocele only when she voids. This means that the trigon is functionally sheared from the internal sphincter, which becomes relatively free and therefore contracts, raises itself above the floor of the trigon and never is stretched downward or opened when the patient voids. This injury may be present with no other evidence of tearing or stretching of the musculofibrous bladder or urethral attachments. Consequently, the following changes occur: hyperplastic

urethritis and even caruncles, a protective mechanism of the internal sphincter due to friction of the mucosa within the spastic sphincter; also, secondarily, there is trigonal congestion with "sheep's wool" changes, i. e., desquamating epithelial cells or simply a passive congestion of the trigon extending over a long period. The presence of a caruncle may indicate dysfunction of the urethra. The liberated urethra shows various degrees of urethrocele. This relative liberation of the urethra is due to more or less complete functional section of the trigonal muscle, when the urethra is pushed upward and forward and its midsection is buckled or curved downward. The fixed external meatus becomes constricted and may occasionally form fibrous tissue and become strictured. Therefore there are a spastic external sphincter, a spastic internal sphincter, congestive trigonal changes, a change in the internal sphincter due to mucosal friction, and often a constricted meatus, fixed by the ligaments so well described by the authors. Dr. D. K. Rose of the Washington University School of Medicine and I have reported a method of repair of this type of injury which can be incorporated in any standard pelvic operation in suitable cases. This method aims to reunite the urethra functionally to the trigon. The operation deals principally with the longitudinal fibers mentioned and consists in inserting our sutures near the meatus, carrying them back to the midtrigonal region; then reinforcing the junction of the urethra and trigon and further reinforcing by repairing any posterior weakness in the bladder supports.

DR. JOSEPH L. BAER, Chicago: Some of these women who have been operated on and reoperated on still have either a complete incontinence or a degree of impairment which is almost as bad as incontinence itself. For these women there appeared in the *American Journal of Urology* approximately half a year ago an excellent and well illustrated article written by Dr. Lowsley. I have tried the operation twice since seeing the article. The last time was before the Chicago Gynecological Society. The essence of the operation is that an incision is made in horseshoe fashion enveloping the urethra and separating it from the symphysis pubis, a downward dislodgement, in other words, of the entire length of the urethra under procaine hydrochloride and epinephrine anesthesia, to which gaseous anesthesia may be added if desired. The entire space between the urethral and para-urethral tissues is dissected away from the symphysis pubis laterally, as wide as need be, until the junction of the bladder and urethra is freely exposed. Then, with the use of ribbon catgut, the lateral columns of the bulbus cavernosus muscles are brought together anterior to the urethra at the vesico-urethral junction in either a single tie or two such sutures, if desirable. Then the tissue over that is closed in the usual fashion and the horseshoe incision likewise closed with interrupted stitches and, if desired, a bit of rubber drainage. It seems to be efficient for those women in whom there has been considerable loss of tissue and in whom previous procedures by way of the vagina have failed.

DR. ARTHUR H. CURTIS, Chicago: From Dr. Royston's discussion I judge there is still some confusion relative to the anatomy of the internal sphincter. The musculature of the bladder wall constitutes the internal sphincter, which is not a circular band at the neck of the bladder but a thickening of the muscle fibers beginning at the neck of the bladder and extending throughout the urethra, reenforced by fibers from the urogenital diaphragm, which constitutes the external sphincter.

Number of Defectives Sterilized.—Of the twenty thousand persons operated on in the United States under the sterilization laws since 1907, the great majority have been mental patients. Only about one third of the total were feeble-minded. It can be readily seen, therefore, that the number of mental defectives sterilized over a period of twenty-three years represents but a small fraction of 1 per cent of the present total in this country. Assuredly, then, sterilization has thus far proved a striking failure as a large-scale measure for cutting off defective stock. —Deutsch, Albert: *The Mentally Ill in America*, New York, Doubleday, Doran & Co., Inc., 1937.

LEVELS OF CONTROL IN THE TREATMENT OF DIABETES MELLITUS

JULIAN D. BOYD, M.D.

AND

ROBERT L. JACKSON, M.D.

IOWA CITY

For twelve years the treatment of diabetes mellitus in children in our clinic has been based on the premise that the diabetic child has normal propensities for health as long as his diabetes is controlled and that therapy should be based on the maintenance of physiologic conditions as far as possible. Prescribed diets have been planned to meet liberally all requirements for growth and activity. The dosage of insulin has been designed to control hyperglycemia at all times. Whereas the instability of the diabetic child does not permit the fullest attainment of this ideal, continuous approximation of normal blood sugar levels has been our criterion in judging the success of management. Effort has been made to avoid glycosuria of any degree as a regular or frequent occurrence. A regimen of management has been evolved which has made such a level of control possible when suitable supervision of the patient is maintained.

When protamine zinc insulin became available and reports of its superiority appeared in the literature, we were led to hope that through its use we might lessen the number of daily injections without lowering the level of control which had previously been established. For over a year the modified insulin has been used for selected hospitalized diabetic children. The regimen provided for strict control of the patient's activities as well as his diet and insulin. Competent laboratory personnel made analyses of all urine passed and of the sugar content of the blood at intervals throughout the twenty-four hours several days each week. Exercise was supervised and standardized as far as possible. From the technical standpoint, the routine employed was adequate to certify the validity of the data obtained. Preliminary to the use of modified insulin, each patient was observed under the earlier regimen with regular insulin, and the requirements of the latter had become essentially stable. The preliminary period averaged four weeks and for some patients was much longer. During this period, once the patient had become aglycosuric a marked decline was noted in the total insulin needed to maintain normal blood sugar levels with a constant diet. Chart 1 illustrates the time factor involved in this process of stabilization and the degree of spontaneous reduction in the requirement of insulin which may be observed. To establish and maintain such stability it was necessary to give from two to four injections daily in accordance with a previously established distribution and to readjust the total dose frequently.

When these patients were transferred to protamine zinc insulin, great difficulty was encountered in attaining levels of control as good as those which had previously been established for the same subjects with regular insulin. If the urine was kept free from sugar the patients tended to have hypoglycemic shock of a type far more severe than that previously observed. With careful supervision it was possible to establish passable control

with the protamine zinc product for the children who required relatively small amounts of insulin; yet even with these children the status was less predictable than when regular insulin was used. At the termination of the study we were forced to conclude that the use of protamine zinc insulin for diabetic children is not compatible with the maintenance of physiologic levels of the blood sugar.

It is not our desire to condemn the use of modified insulins or to close our minds to their ultimate value in the treatment of children with diabetes. Our inability to use protamine zinc insulin successfully must not be accepted as evidence that in the hands of others it may not be used with success. However, other observers have reported difficulties similar to those we have encountered. The discrepancy between the favorable and the unfavorable reports is explainable by the differences in objective of treatment in various clinics or by the level of control maintained in the management of the disease.

At the outset of any discussion of the treatment of diabetes one should distinguish between the elderly patient, whose objective is to pass his declining days in comfort, and the younger patient, who wishes to participate in the various activities of life. Moreover, separate consideration must be given to the child or adolescent patient, who still has a capacity for growth, as opposed to the adult, who has achieved his maximum physique. If the patient offers no prospects of salvage, one may justifiably pursue a passive and lenient form of therapy. If, on the other hand, he has a capacity for health and a fair normality of existence, the physician should feel an obligation to treat the diabetes so effectively that it will offer a minimum of obstruction to his future progress. In treating the child, the routine

Chart 1.—The progressive and prolonged decline in the insulin requirement with a constant diet and maintenance of aglycosuria. The data are taken from the record of an 11 year old girl with diabetes of recent onset. The blood sugar values represent the maximum, minimum and average of nine determinations for each day where indicated.

and plan of control must be especially stringent if the patient is to have an opportunity for normal growth in body and in mind. A regimen which meets all needs of a child can be applied with equal value to the adult patient, whereas a lax or unphysiologic type of management which may be considered appropriate for certain mature patients will prove inadequate and a handicap

in the care of the child. This distinction will not be immediately apparent clinically; the child may subsist without obvious handicap, and the parents and the attending physician may be led to believe that an ineffective regimen is meeting all the patient's needs. Long range studies are necessary to determine the relative worth or safety of different methods of treatment, and many factors must be considered in the establishment of adequacy of control.

In treating the patient with diabetes, one cannot hope for a cure. Under the best of management the patient's defect will persist in a significant degree, and realization of this must be kept uppermost in all future planning. The goal of treatment should be the conservation of the deficient sugar - handling function and the direction of the patient's medical and social status so that

he may lead a full life. The ultimate outcome of the disease will be determined through the adequacy of the regimen to promote normal functioning of the body throughout and to prevent complications and degenerative sequelae. With adequate control the diabetic child has the propensity for normal growth, development and maturation. He will have the strength and ability to participate in the activities of his normal associates as long as they do not conflict with the regimen which his management necessarily imposes. He need not be subject to disastrous complications or sequelae, such as acidosis, diabetic cataracts, gangrene or hepatomegaly, if he adheres continuously to a suitable regimen. With a lax form of management it may appear that all these objectives are being attained; minor depression of growth or the development of degenerative changes may not become clinically apparent for a long period. Leniency in control may please the patient and his parents and may simplify the work of the physician, but ultimately it will result unfavorably for the patient.

The patient's sense of well-being and his clinical manifestations do not offer a safe guide as to the adequacy of his management. His sugar-handling mechanism may be markedly decompensated without causing noteworthy symptoms. The physician must interpret to the patient or his parents the need for continued periodic laboratory studies to confirm the level of control.

Many physicians treating patients with diabetes mellitus have no facilities for the determination of blood sugar and judge the progress of their therapy by occasional urinalyses and the patient's clinical manifestations. Under this type of regimen, glycosuria is common and inevitable. Frequently only a single voiding is tested, and the results do not reflect the status of the patient. Increasing severity of the diabetic state

Chart 2.—Diurnal fluctuations of the blood sugar level in six nondiabetic children receiving diets similar to those of diabetic children but without administration of insulin. Nine determinations were made for each subject during two different twenty-four hour periods. The upper and lower curves represent the maximum and minimum values observed at each hour; the center curve represents the average of the twelve determinations.

will not be detected until it becomes apparent through aggravation of the patient's symptoms. This approach is negative and fails to offer the patient the safeguards which modern methods of treatment make available.

Some clinicians treating diabetes have questioned the harmfulness of mild glycosuria, even though it is persistent. They reason that, if the patient utilizes sufficient sugar for his body's needs, mild wastage can be ignored. This attitude is indefensible when one is out-

to degenerative conditions in the tissues. Certain sequelae of diabetes, such as cataracts, hepatomegaly and xanthoma diabeticorum, are explainable on this basis. Ophthalmologists recognize the fact that the optical characteristics of the eye vary with the sugar content of the body fluids. The increased susceptibility of the diabetic patient to local infections is thought to be related to the effect of a high level of blood sugar. In our series of over 200 diabetic children, the only degenerative complications have occurred in those who had such manifestations at the time they first came under our observation or who failed to follow the prescribed regimen. Those who have shown reasonably good cooperation have not only been free from noteworthy complications and sequelae but frequently have attained a level of health superior to that of brothers and sisters living under the same adverse socio-economic conditions.

Attempts should be made to keep the diabetic patient free from glycosuria at all times and to avoid hyperglycemia. This goal may not be attainable, but the physician may approach it more nearly than is generally recognized. With a constant type of diet and with the doses of insulin distributed suitably throughout the twenty-four hours, the patient should avoid marked fluctuations in the blood sugar level. Under these conditions the physician can instruct the parent to maintain the child's doses of insulin at as high a level as is possible without the production of shock. This routine, checked through frequent urinalyses of samples voided at different times of the day, will safeguard the patient against undetected hyperglycemia. When mild shocks occur, they are easily controlled by the oral administration of minimal amounts of sugar. Such a regimen approximates physiologic conditions as closely as the patient's state will permit.

As a criticism of this strict level of control, the physician may with justice question whether the patient will adhere to such regimentation. We have found that it is no more difficult to work from the stated objectives than from a lower level of treatment. Each patient

Chart 3.—Diurnal blood sugar fluctuations of mildly diabetic children receiving less than 30 units of insulin a day in three or four divided doses. The curves at the left represent seventeen days' study of four subjects who were aglycosuric. The curves at the right represent ten days' study of three patients who were excreting minimal amounts of sugar, not more than 5 Gm. a day. The upper and lower curves represent the maximum and minimum values observed at each hour; the center curve represents the average of all determinations made at that hour.

lining suitable management for the child with diabetes, since it is unnecessary, is theoretically unsound and clinically leads to the complications and degenerative sequelae which characterize uncontrolled diabetes.

Charts 2, 3 and 4 illustrate that even the mildest glycosuria is not compatible with the maintenance of satisfactory blood sugar levels. Chart 2 shows the average diurnal fluctuations in the blood sugar level for a group of nondiabetic children. Chart 3 shows similar values for two groups of mildly diabetic children; some were aglycosuric and others were excreting a daily maximum of 5 Gm. of sugar. Chart 4 offers a similar comparison of blood sugar levels for children with moderately severe diabetes in the absence and the presence of minimal glycosuria.

Glycosuria is the sequel to hyperglycemia. The blood sugar concentration must reach abnormal levels before sugar appears in the urine. Before such levels are attained, the body's defenses will have attempted to prevent them and have failed. Such failure of a physiologic function constitutes a state of decompensation and is associated with pathologic fatigue of the agencies concerned in the maintenance of that function. Such exhaustion of the sugar-handling function accounts for a considerable part of the patient's insulin defect. This can be demonstrated through the degree of recovery observable in the diabetic patient brought under proper control; with the continued use of suitable amounts of insulin, the dose must be successively reduced as the exhaustion component becomes corrected through rest.

With prolonged hyperglycemia, the diabetic patient acquires a higher renal threshold for sugar. As a result he may remain persistently hyperglycemic without noteworthy glycosuria. Abnormally high levels of blood sugar, with or without glycosuria, cannot be considered physiologic, and one may expect that over long periods the chemical alterations in body fluids will lead

Chart 4.—Diurnal blood sugar fluctuations of children with moderately severe diabetes receiving from 30 to 60 units of insulin a day in four divided doses. Six aglycosuric subjects, with a total of nineteen days' observation, provided the data shown at the left; four patients with minimal aglycosuria (an excretion of not more than 5 Gm. in the twenty-four hours), with a total of ten days' observation, were used in the study illustrated at the right. The significance of each curve is as described under chart 3.

finally reaches a stage of compromise between that which is prescribed and that which his home environment makes possible. With the more favored patients, the compromise is a small one. With the noncooperative, economically handicapped or indifferent family,

evidence often indicates that the regimen is being met in minimal degree. Even so, we feel it advantageous to prescribe nothing less than the best for the patient's ultimate interests; if compromise is to be made, let it be made by the patient and his parents, not by the physician. Although the patient may do less than we direct in the way of therapy, he is not likely to do more.

The regimen for treatment of the patient with diabetes should be directed toward the conservation of his resources in their entirety. This implies the maintenance of aglycosuria as far as possible. A regimen which requires or condones glycosuria, even of mild degree, cannot be considered favorable for the patient's ultimate welfare.

ABSTRACT OF DISCUSSION

DR. PERCIVAL ALLEN GRAY JR., Santa Barbara, Calif.: The aim in the management of the diabetic child is to provide a diet adequate for growth and development and to maintain a blood sugar level within physiologic limits. Before the advent of modified insulin four hypodermic injections a day were usually required to realize this aim. Without a fourth, or nocturnal, dose of insulin the child could not consistently maintain a normal fasting blood sugar level. The use of modified insulin has obviated the necessity for so many doses. The policy at the Santa Barbara Clinic has been to administer before breakfast the least amount of protamine zinc insulin necessary to control hyperglycemia during the ensuing night. When this amount has not also sufficed to control hyperglycemia during the day, supplementary doses of unmodified insulin have been given. Few of the children have been able to stay controlled with one dose of protamine zinc insulin a day. The majority have required at least one supplementary dose of unmodified insulin, which has usually been given at the same time in the morning. This program has reduced the danger of unrecognized hypoglycemic shock to a minimum. The necessity of giving a quick-acting insulin with the more slow-acting preparation is occasioned by the delayed absorption of the latter. Since histon insulin contains a greater proportion of free insulin per unit volume than does protamine zinc insulin, it does not have to be supplemented with unmodified insulin as often. Each preparation is capable of controlling juvenile diabetes when used alone. However, in many instances the amount required may be so great as to subject the patient to a grave risk from hypoglycemic shock. This risk is increased by the unpredictability of the absorption of modified insulins. One is often forced to weigh the risk of chronic hypoglycemia against that of chronic glycosuria. Many patients are not suited to treatment with modified insulin and must return to multiple doses of unmodified insulin. Some patients do well only if their modified insulin is supplemented by multiple doses of unmodified insulin. One wonders what advantage accrues if the child requires three or four injections anyway. I agree with the authors that protamine zinc insulin has been something of a disappointment in the treatment of juvenile diabetes cases. Not only has it frequently failed to prevent the characteristic wide fluctuations in the blood sugar level, but it has produced some troublesome local cutaneous reactions. Some children who at first did poorly with protamine zinc insulin did well later when their diet was changed. At present my associates and I consider from 200 to 225 Gm. of carbohydrate the upper desirable limit for patients receiving modified insulin. This carbohydrate allowance is given one fifth for breakfast and two fifths for each of the other two meals. Bedtime nourishment has been insisted on to protect against hypoglycemia during the night. I feel strongly about negligent treatment of diabetic children, but much of my early fear about the deleterious effects of mild, even though persistent, glycosuria has faded. Children seem to grow at a normal rate, pass successfully through accidents and illnesses, avoid the classic complications of diabetes and lead happy and useful lives in spite of never being exactly sugar free.

DR. LEONA M. BAYER, San Francisco: This paper seems important in relation to certain problems which I have found

in the care of diabetic children at Stanford University Hospitals. With so much medical publicity in newspapers, a curious situation seems to be springing up, in which the burden of proof is on the physician who does not immediately subscribe to all the newest methods. Thus the physician who says that protamine zinc insulin is often not appropriate or that strict control is valuable, in spite of much discussion of free regimens, is sometimes put on the defensive. For this reason such a critical evaluation of the effect of protamine zinc insulin based on a preliminary demonstration of the changes in the level of control under careful supervision with regular insulin seem to me most valuable. Before the long time value of strict versus less rigid control can be definitely proved, longitudinal studies on diabetic children are needed for comparison with the normal growth studies which are now coming out of child study institutes.

DR. J. D. BOYD, Iowa City: With the use of regular insulin and a strict regimen of management, an excellent level of diabetic control can be maintained, with essential freedom from glycosuria, even with the severely diabetic child. Protamine zinc insulin can do no more than this, and in our hands it has been less effective. However, we are concerned less with the problems of protamine zinc insulin than with urging adherence to higher standards of treatment for the child with diabetes mellitus.

GASTRODUODENOSTOMY FOR CERTAIN DUODENAL ULCERS

HOWARD M. CLUTE, M.D.

AND

JOHN S. SPRAGUE, M.D.

BOSTON

Although the operation of gastroduodenostomy was suggested in 1892 by Jaboulay¹ and first applied in 1898 by Henle,² it has received no widespread application and in fact is unknown to many surgeons. This is a curious circumstance to us, for although gastroduodenostomy is by no means a panacea for all duodenal ulcers, there are certain situations in which it can be readily applied with most satisfactory results. It is not our intention at this time to enter the controversy which still continues regarding the relative advantages

Fig. 1.—Degrees of free and combined gastric acidity for five patients before (hollow blocks) and after (solid blocks) lateral gastroduodenostomy.

of short-circuiting operations and some type of gastric resection for duodenal ulcer. It is generally recognized that duodenal ulcers which finally require surgical intervention because of the failure of medical treat-

ment or because of the occurrence of complications during their course cannot all be managed by any one surgical procedure. The surgeon must be prepared in each case to apply the operation best adapted to the conditions encountered. Some patients should certainly have a subtotal resection of the stomach, and for others it is recognized that some type of short-circuiting operation is best. Gastroduodenostomy is one of the short-circuiting procedures which has an occasional place in the surgical treatment of duodenal ulcer.

Since the successful beginning of gastrointestinal surgery in 1881, with Woelfler's gastrojejunostomy and the Billroth I gastric resection, many operations for the treatment of duodenal ulcer have been devised. Surgeons at first concerned themselves chiefly with gastrojejunostomy and various combinations of this operation with gastric resection. Later they focused their attention on operations involving only the stomach and duodenum, including the pyloroplasties described by Heineke in 1886, Finney³ in 1902 and Horsley⁴ in 1919.

Jaboulay¹ in 1892 first suggested anastomosis of the stomach and the second part of the duodenum. He pulled the anterior surface of the stomach down and over to the right, so that the anastomosis was difficult

Fig. 2.—Mobilization of the second part of the duodenum by cutting the parietal peritoneum at its posterior border is the first essential in gastroduodenostomy.

of performance and resulted in tension on the suture line. Villard⁵ in 1900 reported an easier modification, much more like the one we use today, in which the duodenum was made to anastomose with the right end

of the greater curvature of the stomach. Theodor Kocher⁶ in 1903, however, was the first to mention specifically the feature of modern gastroduodenostomy which makes its performance so easy and so satisfactory: complete mobilization of the second part of the duodenum simply by incision of the parietal perito-

Fig. 3.—The wrong way to turn the duodenum over to the stomach. When the lateral side of the duodenum is grasped rotation occurs, with resulting obstruction.

neum lateral to it. It is of interest that Kocher, master surgeon, wrote of gastroduodenostomy: "We regard it as the normal procedure, and we are of the opinion that it will take precedence over all the previous methods of gastro-enterostomy and pyloroplasty." The operation of Villard as modified by Kocher and the procedures described by Balfour⁷ in 1918 and by Moynihan⁸ in 1921 differ in only minor particulars from the technic we follow today.

Rienhoff⁹ in 1932 described an "infrapapillary gastroduodenostomy," in which the gastric contents are emptied into the duodenum well below the papilla of Vater. It is not apparent to us that sufficient advantage comes from entering the duodenum in its third part rather than its second to warrant the added dissection necessary to mobilize it.

Much work has been done on the subject of gastric acidity and its changes after various stomach operations, particularly those designed for relief or cure of duodenal ulcer.

Walters,¹³ J. M. T. Finney Jr.¹⁴ and others agree, that the reduction in acidity often obtained after pyloroplasty, gastroduodenostomy or gastrojejunostomy and even that following subtotal gastric resection is due chiefly to regurgitation of the duodenal contents. Furthermore, as Wilhelmj, Henrich and Hill¹⁵ have pointed out, the efficiency of duodenal secretions in lowering the acidity in the stomach is perhaps due 75 per cent to simple dilution and only 25 per cent to neutralization. Hill and his associates, using dogs, showed that the increase in duodenal regurgitation was maximal after gastroduodenostomy, more than after either gastrojejunostomy or pyloroplasty.

From the physiologic point of view it would appear logical to empty the acid gastric secretion into the duodenum rather than into the jejunum. It is now common clinical knowledge that the farther away from the pylorus the gastric juice enters the intestine, the greater the chance for suture line ulceration. This has recently been again confirmed in the laboratory by de Bakey.¹⁶ He showed by a series of experiments that, with gastrointestinal anastomosis, ulceration occurred in a steadily rising percentage of cases when increasing quantities of the bile, pancreatic juice and succus entericus were removed from the area of the suture. He found suture line ulcer in 100 per cent of those animals in which no bile, succus entericus or pancreatic juice reached the suture line. In view of these and similar experiments it would seem that gastroduodenostomy should seldom be followed by anastomotic ulcer

lowered by gastroduodenostomy, however, is by no means clear from our results.

The accompanying chart of gastric acidity for five of our patients who had gastroduodenostomy shows no evidence of adequate dilution or neutralization of gastric acidity. As may be seen, the total and free acid from months to years after operation was nearly as high as or

Fig. 5.—The duodenum brought up toward the greater curvature of the stomach, which is now readily laid against it.

Fig. 4.—The proper way to lift the second part of the duodenum bodily over toward the stomach. When adequate mobilization has been secured this can be done with no tension whatever on the duodenum.

and should be a valuable means for neutralizing high gastric acidity by permitting alkaline duodenal contents readily to enter the stomach. That gastric acidity is

was higher than it had been before operation. This we find very surprising, since all the patients are clinically apparently well and recent x-ray studies show no evidence of any pathologic change.

Theoretically, anastomotic or suture line ulcer either should not occur or should be very infrequent after gastroduodenostomy, but in actual practice it occasionally does occur. We doubt that it is frequent, but it is difficult to obtain any statistics. Moynihan never saw secondary ulceration. J. M. T. Finney Jr. said that anastomotic ulcer does not follow gastroduodenostomy. Flint¹⁷ in a study of 200 operations, did not see this complication. We have had no evidence of suture line ulcer in our fifteen cases.

That suture line ulcer may follow gastroduodenostomy, however, is attested by Wilkie's¹⁸ report in 1933 of two cases in a series of 159 gastroduodenostomies. He said, however, that in both cases the ulcer responded immediately to later gastrojejunostomy. More recently Graham¹⁹ reported one stomal ulcer in his experience with nine gastroduodenostomies. We have therefore positive evidence from the literature of only three stomal ulcers after nearly 400 operations, an incidence of less than 1 per cent. Allowing for inaccuracies, this is still a considerably lower incidence of stomal ulcer than the 8.5 per cent reported in England by a careful collective inquiry into gastrojejunal ulcer after posterior gastro-enterostomy.²⁰

Gastroduodenostomy has thus far been most satisfactory in our experience in the relief of pyloric stenosis. We have used it in seven cases of this condition in the last three and a half years, with results that have been most satisfactory. Four of the seven patients were in a serious condition when admitted to

Fig. 6.—The posterior layer of silk sutures has been inserted; the stomach and the duodenum have been opened, and the inside layer of sutures is started.

our service. They were all over 50, one being 67. The four all showed clinical and chemical evidences of their long-standing obstructions. One patient, a woman, was confused, disoriented and semicomatose, with a high nonprotein nitrogen content, a high value for carbon dioxide and a low content of blood chlorides. We spent ten days preparing her for operation, and in addition to a gastroduodenostomy we did a jejunostomy, by means of which immediate postoperative feeding was given. We have repeatedly used jejunostomy for feeding in cases of serious involvement of the stomach and are convinced that it is a valuable adjunct in their management.

The postoperative course of these patients with obstruction was surprisingly comfortable. Almost no vomiting occurred, and gastric drainage by Levine tubes was usually unnecessary after a few hours. Their course seemed to us much smoother than that of patients with a similar involvement who had had a posterior gastro-enterostomy.

All these patients are still feeling well after intervals of six months to three years. Roentgenograms show the new stoma working well, with varying amounts of barium sulfate going through the pylorus. Four had their gastric acidity checked a year or more after operation. To our surprise it was higher than normal in three cases and normal in the fourth. This fact causes us some concern as to future possibilities in spite of the present comfortable clinical status of the patients.

We have used gastroduodenostomy for two patients, both men, who had persistent pain from duodenal ulcer in spite of long medical treatment. They have been

relieved of their symptoms and apparently are doing well one and two years, respectively, after operation, although one showed a high value for total acid when examined a year after operation. This man's fluoroscopic examination showed most of the barium sulfate going through the new opening and a two to three hour emptying of the stomach. Because of the high gastric acidity persisting after operation in this case and in others we have observed, we are hesitant to use this operation for the nonobstructed duodenal ulcer for which medical management fails, in spite of the present comfort of both these men. We would, we believe, feel much more optimistic as to their future if we had done a subtotal gastrectomy.

We have done gastroduodenostomy for two male patients with duodenal ulcer who had had serious hemorrhages. One of these has remained entirely comfortable and very well for over two years. The other patient died a few hours after operation.

There is an increasing tendency among surgeons to operate when there is massive hemorrhage from duodenal ulcers if the patient's condition warrants and to resect the stomach and the ulcer if possible. We are in agreement with this policy when it can be followed, but certainly we believe that in many hands radical resection of the stomach just after acute bleeding will carry a serious mortality. Furthermore, it is well known that in occasional instances a short-circuiting operation has been beneficial. Gastroduodenostomy may permit one to view the bleeding ulcer when the duodenum is opened and may permit suture of its base. This procedure is certainly not ideal for the complication, but we believe that for certain bleeding ulcers

Fig. 7.—From a recent case of gastrojejunal and duodenal ulcer in which repeated serious hemorrhages occurred. In such cases the gastrojejunostomy must be taken down, the jejunum closed and either a subtotal gastrectomy performed or some other procedure like gastroduodenostomy done to overcome pyloric spasm and obstruction.

the patient's condition, the ulcer's location and the surgeon's abilities combine to make it a most useful operation.

In two cases we have combined gastroduodenostomy with the resection of an ulcer very high on the lesser curvature of the stomach. The first operation was

done over two and one-half years ago; the patient was a man of 58 and has been repeatedly examined by x-rays and gastroscopy. For a year after operation he was well in every way and his ulcer had healed. He then had a return of the ulcer in the lesser curvature, where it was previously excised. There has been much question as to whether or not it is malignant, but since it has not changed in some months it is apparently benign. The other patient was a girl of 18 with a perforating ulcer very high on the lesser curvature, which we felt was too indurated to permit subtotal gastrectomy. Her operation was recent and she is still doing well.

From these experiences we feel that we cannot recommend, as first choice, gastroduodenostomy and local resection of ulcers high on the lesser curvature. We believe they should have subtotal resection of the stomach if feasible. If resection is not safe, however, as in our second case, we believe that local resection by knife or cautery, plus some short-circuiting procedure, is the only choice.

Gastroduodenostomy has been particularly helpful to us in the successful management of two bleeding gastrojejunal ulcers. Our experience with such ulcers has frequently been distressing because of the extensive surgical procedures necessary to cure them. Ideally certain fundamental steps are desirable and necessary. One must (1) remove the jejunum from the stomach, (2) remove any ulcer from the jejunal wall and close the jejunum and (3) overcome pyloric obstruction and high gastric acidity either by resection of the stomach or by some short-circuiting procedure.

The addition of a subtotal gastric resection and a Polya or other anastomosis to the removal and repair of the jejunum is at times, in our opinion, too much surgical intervention. We have in the past, in one case, taken down the gastro-enterostomy and left the duodenum alone. The patient, a man, later had severe pyloric obstruction, had a gastric resection elsewhere and died. It is apparent to us, therefore, that after the reduction of a gastro-enterostomy relief of pyloric spasm and obstruction must be assured by either a plastic operation on the pylorus or a subtotal gastric resection. We prefer, and carry out, resections of the stomach when feasible. In the two cases recorded here, however, repeated severe bleeding had so depleted the patients' strength that they were poor operative risks and we feared that subtotal gastrectomy would prove too radical a procedure. Gastroduodenostomy was followed by complete relief for three years in one case and by very satisfactory relief for two years in the other. The second patient still has a high gastric acidity and recently had some heartburn, which was relieved by a few alkaline powders.

TECHNIC

The proper development of gastroduodenostomy technically is entirely dependent on an adequate mobilization of the second and at times even the third part of the duodenum. Unless one has seen or tried mobilization of the second part of the duodenum one has no conception of the ease with which it can be done or of the degree to which the duodenum can be brought up from its bed around the head of the pancreas.

We prefer a retracting incision of good length in the upper part of the right rectus muscle. This permits either gastroduodenostomy or, if need be, any other

operation on the stomach. The stomach and colon are retracted and walled out of the field by gauze pads. Other gauze pads are placed over the inferior surface of the liver, which is now retracted. The peritoneum, just lateral to the duodenum, is incised (fig. 2), and since this layer is almost bloodless it can rapidly be freed from the cellular tissue beneath it. The duodenum should be freed well up around the first part and down as far as is necessary to permit it to lie readily against the stomach, the surgeon using care not to be too rough and so cause bleeding in the adjacent pancreatic tissue.

When the duodenum has been adequately freed it is possible to lay it with no tension whatever and with no rotation or twisting of its lumen against the greater curvature of the stomach in the prepyloric area.

Fig. 8.—The defect in the stomach left after detaching the jejunum has been closed. The jejunum is to be closed next by suturing it transversely.

Figure 3 shows the wrong way to lift up the duodenum. The clamp has been applied to the outer border of the second part of the duodenum, and as this pulls it upward it inevitably must roll the duodenum and so narrow its lumen. Figure 4 shows the correct way to lay the duodenum against the greater curvature of the stomach by placing Allis clamps along its superior border. When the duodenum has been sufficiently mobilized, no obstruction to its lumen results from the procedure.

It is our belief that certain reports in the literature of the occurrence of serious difficulties immediately after gastroduodenostomy, such as persistent vomiting and obstruction, are perhaps related to the fact that the duodenum was rotated when it was laid against the stomach instead of being lifted bodily over to the greater curvature of the stomach.

Figure 5 shows a stay suture placed at the superior end of the duodenum, near the pylorus, and holding forceps bringing the greater curvature of the stomach

and the mesial border of the duodenum together for the placing of the stay suture at the lower end of the anastomosis. Figure 6 shows the posterior layer of sutures, which we always place with fine silk, already finished. The stomach wall has been opened, any bleeding vessels have been caught and tied, the duodenal wall has been opened, and the second layer of sutures, which we make with fine chromic catgut, is just being started.

We do not use clamps for gastroduodenostomy. In the first place it is difficult or impossible to place them,

Fig. 9.—The gastroduodenostomy passageway being made after the jejunum has been removed from the stomach and the defect in the greater curvature of the stomach closed. Subtotal gastrectomy added to these preliminary procedures may be too much surgical intervention for the patient. Gastroduodenostomy can be quickly and easily done with much less shock and will overcome pyloric spasm and obstruction.

and in the second place we like to see any bleeding vessels so that we can catch them individually and tie them.

We use the greatest care in walling off the entire abdomen, especially the subphrenic and subhepatic areas, before opening the stomach or duodenum. By the constant use of suction we prevent to a great degree any soiling of the area.

The gastroduodenostomy suturing is now finished, just as in any gastrointestinal anastomosis, and, when the outer layer of silk sutures is completely in place, bits of omentum are brought in and tied over the suture line to make further protection.

Figures 7, 8 and 9 show the use of gastroduodenostomy in the complicated surgical technic necessary for the cure of gastrojejunal ulcers. The jejunum is first separated from the stomach, as shown in figure 8, and the defect in the greater curvature of the stomach is closed by a double layer of sutures. The defect in the jejunum is now closed by suturing the longitudinal hole transversely after the Heinecke-Mikulicz method. In figure 9, one can see the outline of the defect made in the greater curvature of the stomach by closing the opening which was previously anastomosed to the jejunum. One sees also, in this schematic drawing, the first row of sutures placed in the gastroduodenostomy, and one notes the location of the open-

ings in the greater curvature of the stomach and the second part of the duodenum, which are to be joined.

In conclusion, then, we would urge that gastroduodenostomy be given more consideration when surgical treatment is necessary in the management of certain duodenal ulcers. Although opinions and experiences as to the occurrence of stomal ulcers after gastroduodenostomy differ widely, we have been unable to discover evidence of a high percentage of these post-operative complications. We believe that gastroduodenostomy results in a nearer approach to normal gastric physiology than other short-circuiting operations. Our clinical experiences with this operation have been very satisfactory.

171 Bay State Road.

ABSTRACT OF DISCUSSION

DR. ROBERT S. DINSMORE, Cleveland: The authors have called attention to an operative procedure which is not in common use. Obviously this procedure has the advantage that any pyloroplasty does, in that it cannot be followed by a jejunal ulcer and that in most hands it would have a lower mortality rate than gastric resection. Theoretically it should offer the advantage of emptying the gastric secretion into the duodenum rather than the jejunum. Moynihan has cited three types of cases which prevent this operation from having a wide application: first, cases in which there is a large active ulcer of the duodenum accompanied by infection and edema in the surrounding areas; second, cases in which the duodenum is immobile because of chronic adhesions either from a previous ulcer or from disease of the gallbladder, and, third, cases in which there is an obstruction by the third portion of the duodenum as the result of pressure from the superior mesenteric artery or the right or middle colic artery and tuberculous glands. In the United States the incidence of tuberculous glands is low, and from a practical standpoint the third type of case is not as important as the first two. Moynihan also made the point that the convalescence of the patient is not as smooth as after an ordinary gastro-enterostomy. This has not been the experience of Dr. Clute and Dr. Sprague. Cases of the types cited, with the small number of cases of duodenal ulcer which are referred to the surgeon by the gastro-enterologist, leave a limited number to which the operation may be adapted. At the Cleveland Clinic during the past year only 5 per cent of the patients with duodenal ulcer came to the surgeon. I am in accord with the authors when they state that the operative procedure for the cure of a gastrojejunal ulcer may be a formidable task. Immobilization of the ulcer itself in some instances is difficult. In addition there must follow resection of the ulcer, resection of the stomach, closure of the duodenal stump and anastomosis of the jejunum to the stomach. Occasionally the anastomosis has to be made at a site which is not adaptable to the opening in the jejunum, which follows the resection of the ulcer. If possible it would be a great advantage to do the simple procedure which the authors used in their two cases. A striking fact is that in the 400 collected cases there were only three stomal ulcers. This perhaps supplied the greatest argument for the use of this procedure.

DR. HAROLD LINCOLN THOMPSON, Los Angeles: Dr. Clute and Dr. Sprague have made a definite contribution to American experience with gastroduodenostomy. They stated that the operation should be limited to selected cases. All their cases were complicated, and despite the fact that they did not observe a lowering of acidity and their suggestion that subtotal resection might have been preferable in some instances, the clinical results were good. Since Jaboulay first suggested gastroduodenostomy forty-six years ago the operation has not come into general use because of certain technical difficulties and the widespread use of gastrojejunostomy. Gastrojejunal ulcer has brought the latter operation into current and growing disfavor. For this reason the attention of American surgeons has been directed toward plastic or other short-circuiting operations. In continental

Europe subtotal gastric resection is widely used in the treatment of duodenal ulcer. In spite of certain objections this procedure has a firm physiologic basis. The surgeons who have had the greatest experience with gastroduodenostomy are Flint of Leeds and Wilkie of Edinburgh. Flint has used the operation almost exclusively in 200 cases, whereas Wilkie has used it in approximately 160 cases. The critical remarks of Wilkie are noteworthy because he also uses other forms of operation in the treatment of peptic ulcer. He employs the operation for recurrent irritable ulcers with hypersecretion in patients whom he considers unsuitable for gastrojejunostomy. His results do not equal those of gastrojejunostomy. The results were excellent with 64 per cent of his patients, and an additional 25 per cent were relieved but not cured. Stomal ulcer was present in two instances. There is a difference of opinion regarding the effect of gastroduodenostomy on the secretory and motor functions of the stomach. I have conducted extensive studies on the effects of various surgical procedures on these functions. In 1932 I reported the effects of graduated resection of increasing portions of the pylorus in dogs. I observed a reduction in acid values directly proportional to the amount of pylorus removed. At the same time I made observations on gastroduodenostomy. In the gastric contents, after a meat-water test meal or the injection of histamine, the hydrogen ion concentration was not reduced. However, according to fractional analysis the volume of gastric contents is increased and the emptying time of the stomach is prolonged. The amount of bile in the gastric contents also is increased. I have employed gastroduodenostomy in the treatment of twelve patients with complicated peptic ulcer. Despite careful selection of cases, there was one death. Otherwise the clinical results were good.

DR. M. E. STEINBERG, Portland, Ore.: The authors' remarks on the physiology and the anatomic relationships of gastroduodenostomy are in agreement with clinical experience and some experimental evidence. It remains for me to emphasize that an extensive mobilization of the duodenum entails certain dangers. The stomach, filled with bile, pancreatic juice and blood, pulling the duodenum to the left side, may kink it on the mesocolon or the root of the mesentery. Some fatalities due to a high duodenal obstruction have been reported after a Finney-Haberer gastric resection. There is some troublesome retention and vomiting after the Finney-Haberer modification of the Billroth I stomach resection. The mobilization of the duodenum, which is pulled to the left side by the stomach, may also pull or twist the common duct and produce pancreatitis. I have performed eleven gastric resections of the Finney-Haberer type in suitable cases with excellent results. This operation is contraindicated for fat patients because the blood supply on the outside of the duodenum is extensive and the mobilization more difficult. A gastroduodenostomy or a Finney-Haberer resection will not prove successful in the presence of stasis in the duodenum. I have performed 131 stomach resections, with three fatalities. Two of the fatalities were in connection with a secondary operation for jejunal ulcer and only one in connection with a primary resection. I believe that a gastroduodenostomy should give good results in a certain percentage of cases. In view of my experience I must remain satisfied with the resection in preference to any indirect procedure, hoping that the results in the future will be as favorable as they have been in the past.

DR. HOWARD M. CLUTE, Boston: The postoperative obstruction following gastroduodenostomy, to which Dr. Steinberg refers, has been reported frequently in the literature and has been in the past a common and serious complication of the operation. I believe this difficulty is due to rotation of the duodenum as it is laid against the stomach. This we have studiously avoided in our cases, as shown in the artist's drawing. In our experience vomiting after gastroduodenostomy has not been a problem. I do not wish to leave with you the impression that I consider gastroduodenostomy a panacea for all duodenal ulcers and believe that it will replace all other methods of treatment. I do, however, wish to emphasize three situations in which this operation has been helpful to us. 1. Gastroduodenostomy with local anesthesia has been technically easier

for me than posterior gastro-enterostomy in treating certain very sick patients with long-standing and severe pyloric obstruction. 2. In certain cases of serious hemorrhage from a duodenal ulcer gastroduodenostomy may be life saving. It may permit vision and suture of the bleeding ulcer as well as relief of the pyloric obstruction. 3. In occasional cases of bleeding gastrojejunal ulcer, gastroduodenostomy can safely replace gastric resection after the gastrojejunal ulcer has been removed. By this lesser procedure the operative shock is lessened and yet the pyloric obstruction and spasm related to the original duodenal ulcer are relieved.

Clinical Notes, Suggestions and New Instruments

DIPHTHERITIC INVOLVEMENT OF THE LIPS, WITH ABSENCE OF SIGNS IN THE NOSE AND THROAT

H. JERRY LAVENDER, M.D., AND JOHN B. SQUIRES, M.D.
CINCINNATI

No mention can be found in the literature of cases in which diphtheria involved the lips and buccal membranes alone, with repeated negative clinical signs in the nose and throat. Believing this to be the first report of such an involvement, we present the following report:

J. M. W., a colored girl aged 10 years, was admitted to the children's burn ward at the Cincinnati General Hospital Oct. 16, 1937, with an extensive (60 per cent total body area) second and third degree burn from fire. The face and neck were spared. She was in deep shock. Intravenous dextrose and a blood

Fig. 1.—Diphtheria of lip, showing ulcerous area seventy-two hours after onset.

transfusion were given immediately, along with other anti-shock therapy. In view of the extent of the burn, she did well; daily transfusions were given and the burned areas were treated locally with wet dressings of solution of aluminum acetate and green soap tub baths as soon as the patient could tolerate them. Cultures of material from the nose and throat on the second day were negative for Klebs-Loeffler bacilli.

At midnight October 27 (the twelfth hospital day) swelling of the lower lip was noted. Eight hours later two thirds of

From the Department of Dermatology and Syphilology, Pediatric Division, Cincinnati General Hospital.

the lower lip was involved in a granular lesion covered with a tough whitish membrane. On the right buccal mucous membrane were similar small round patches. A stained smear (carbol gentian violet) showed many short chained cocci but no fusiform bacilli.

On culture of material from the area, hemolytic streptococci and staphylococci were found. Culture of material from the nose and throat were again negative for Klebs-Loeffler bacilli. Within twelve hours an area in the center of the lower lip 1 cm. in width and 1 cm. in depth began to slough, and sloughing was complete within twenty-four hours. The surface of the ulcer was now smooth and a deep red and involved the entire lower lip. Sulfanilamide was given in 5 grain (0.3 Gm.) doses four times a day. Ten cc. of polyvalent antistreptococcus serum was given intravenously along with 5 minims (0.3 cc.) of epinephrine, 10 cc. of calcium gluconate and 200 cc. of physiologic solution of sodium chloride. The next day another culture of material from the area of the lip was morphologically positive for Klebs-Loeffler bacilli; that from the nose and

also showed Klebs-Loeffler bacilli. The lip was healing nicely but ulceration of the gums was more marked. At no time was there any membrane or any clinical evidence of diphtheria in the nose or throat. Diphtheria antitoxin was again given. On the fortieth hospital day the use of a 2 per cent aqueous solution of gentian violet on the gums was begun. Cultures continued to be positive for Klebs-Loeffler bacilli. Within another week, however, the lip and gums were entirely healed and cultures became negative and remained so. Progress was noted in the healing of the burned areas.

The salient points in this case were:

1. Diphtheritic involvement of the lips with ulcerations.
2. Diphtheritic involvement of the buccal membranes.
3. Diphtheritic involvement of the gingival area.
4. Positive virulence test with Klebs-Loeffler bacilli from the lips and buccal membranes.
5. The finding of Klebs-Loeffler bacilli from tooth sockets (alveoli).
6. Consistently negative clinical signs in the nose and throat.
7. Consistently negative cultures for Klebs-Loeffler bacilli in the burned areas.
8. Healing of ulcerous area, and recovery.

717 Provident Bank Building.

Fig. 2.—Healed upper and lower lips one month after onset.

throat was still negative. The temperature ranged from 99.4 to 101.8 F. Progression of the lesion ceased. On the fifteenth hospital day polyvalent antistreptococcus serum was given as before. Repeated cultures of material from the nose and throat were negative for Klebs-Loeffler bacilli, while cultures from that of the lesion of the lips were positive. On the twenty-first day a virulence test of the organism from the labial lesion was reported positive. At this time the lesion involved the right side of both upper and lower lips and extended onto the lower gums. No ulcerations were seen on the buccal mucous membrane. Careful vaginal examination revealed no ulcers or scars. The white blood cells numbered 34,050 with 60 per cent polymorphonuclear neutrophils and 34 per cent lymphocytes. Diphtheria antitoxin, 10,000 units, was administered intramuscularly. On the twenty-third day a culture of material from the throat was reported positive for Klebs-Loeffler bacilli for the first time and negative for hemolytic streptococci. Cultures from the burned areas were negative for both. The ulceration of the lip was healing somewhat but the process was extending along the lower alveolar ridge. The patient had a spiking type of temperature, but no evidence of pulmonary or renal infection was found. Repeated blood cultures and Kahn reactions were negative. On the thirtieth day two lower incisor teeth became so loose that the patient extracted them herself. Cultures from material in these sockets

AN UNEXPECTED ELECTROCARDIOGRAM OF THE FETUS

ALLEN S. JOHNSON, M.D., SPRINGFIELD, MASS.

Electrocardiograms of the human fetus in utero are apparently comparatively rare; a search through the *Quarterly Cumulative Index Medicus* for the past five years discloses no references in the literature except for the work of Strassmann and his associates¹ in Germany in 1933, which was summarized by Strassmann² in this country in 1936. Sachs³ had reported such studies in 1922, as did some Japanese workers⁴ seven years later.

There are two possible explanations for the rarity of such observations in the face of the immense amount of electrocardiographic material now available. The galvanometric deflections of the electrocardiogram of the fetus are so faint that they defy detection unless the base line is smooth and entirely free of oscillations. And even with an ideal graphic background the human fetal heart and the corresponding cardiac current are too weak to appear in a routine electrocardiogram, as Strassmann² has pointed out. Nor did the use of a rectal or a vaginal electrode insure satisfactory results. After experimenting on pregnant domestic animals, Steffan and Strassmann¹ evolved a special apparatus and technic which enabled them to secure electrocardiograms of the human fetus late in pregnancy. The reasons for reporting the following case are twofold. Electrocardiograms of the fetus are still something of a medical curiosity; secondly, these tracings, in contrast to the foregoing, were obtained while a routine four lead electrocardiogram on the mother was being taken with an audion tube type of machine (Sanborn cardiette), which is in common clinical use throughout the country.

REPORT OF CASE

Mrs. B. M., a primipara aged 19, almost at term, was referred by Dr. A. F. G. Edgelow because of a pronounced cardiac irregularity of one month's duration. The patient herself was unaware of this arrhythmia and the pregnancy had otherwise been without incident. Clinical examination suggested

a sinus arrhythmia, and an electrocardiogram was taken for confirmation. In the course of routine measurements, regularly recurring negative deflections about 0.5 mm. deep were encountered in leads 2, 3 and 4F (apex and left leg). These may be located by the arrows in the accompanying illustration. They were absent from leads 1 and 4R (apex and right arm) presumably because this electrical axis did not pass sufficiently close to the mother's pelvis to pick up the fetal currents. These fetal electrocardiographic deflections were at first thought to be artefacts, and a well known cardiologist was quite emphatic on this point, though it must be admitted that he was not told of the patient's pregnancy when the tracings were submitted. The true nature of these minute deflections became

The arrows point to the fetal deflections.

apparent when it was found that their frequency corresponded to the fetal heart rate. This opinion was subsequently confirmed by Drs. Paul D. White and Burton Hamilton of Boston.

In contrast to the tracings published by Strassmann,² the electrocardiogram in the present case showed slight changes in the fetal heart rate in lead 2. The patient was delivered of a normal full term child thirteen days later, but at the time of discharge from the hospital she still showed a marked sinus arrhythmia.

In the illustration unfortunately it is almost impossible to identify the fetal cardiac deflections even though they are located by means of arrows. Some of them may be detected by means of a 5 power lens and the rest must be taken on faith although they were quite obvious to the naked eye on the original tracings.

A CASE OF CHIARI'S NETWORK ASSOCIATED WITH A MURMUR RESEMBLING THE BRUIT DE ROGER

ROBERT WILSON, M.D., CHARLESTON, S. C.
Professor of Medicine, Medical College of the State of South Carolina

This singular cardiac anomaly was first described in 1897 by Chiari,¹ who reported a series of eleven cases in which he found a peculiar network of fibers occupying the right auricle. This network he considered a developmental anomaly consisting of an incomplete residuum of the valvula venosa dextra and the septum spurium, which are represented only by threads attached to the eustachian and thebesian valves on the one side and to the crista terminalis or to the region of the tuberculum loweri on the other. The published reports would seem to indicate that the anomaly is very rare, although Yater² estimates that it occurs in from 2 to 3 per cent of hearts which are otherwise normal developmentally and Helwig³ concludes that such reticula are "found to be present in 1.5 per cent of routine autopsy examinations." Probably it would be found more frequently if it were systematically looked for. Yater,² who has discussed the abnormality fully, collected from the literature twenty-five cases in addition to those reported by Chiari, four of which he himself had described, and reported still another case of his own. In no instance had the diagnosis been made prior to death, and in only one case had any physical signs been observed which might be attributed to the network. This case was reported by Alvarez and Herrmann⁴ in 1931. These authors noted a "most peculiar low pitched thonging murmur heard along the right sternal border from the third rib region downward," which had a musical quality "and faded off into a distant purr." It resembled the venous souffle which is heard at times over the jugular bulb. The diastolic murmur of aortic regurgitation and a characteristic Austin Flint murmur were also heard. Some doubt has been expressed as to whether the murmur in this case actually was produced by the network, as assumed by Alvarez and Herrmann, since there were other more common pathologic conditions present. The general opinion is that the network produces no symptoms or signs and is of interest clinically only as affording an occasional source of pulmonary embolism.

The following typical case of this congenital defect came under my observation in May 1937 and is of especial interest because of the presence of a murmur almost identical with that described by Alvarez and Herrmann, which suggests the probability that the network at times may give rise to an auscultatory sign.

REPORT OF CASE

J. M., a Negro fisherman, aged 40, was admitted to the medical floor of the Roper Hospital May 3, 1937, five days after his discharge from the surgical floor, where he had been treated for extravasation of urine. His previous history included syphilis and gonorrhea, and at the age of 30 he had an illness characterized by migratory arthritis. There was no history of previous heart disease. The diagnosis on admission was pneumonia. On physical examination fine rales were heard scattered over the right side of the chest anteriorly, in the left axilla and in the left side of the chest posteriorly from the third to the sixth rib. The blood pressure was 220 systolic, 130 diastolic; the arteries were thickened. The heart was enlarged and a systolic murmur at the apex transmitted to the left axilla and gallop rhythm were noted. The chief interest was centered on a continuous humming murmur with systolic accentuation at the sternal end of the fourth and fifth left interspaces, which resembled the so-called venous hum. The area of distribution was quite limited, the murmur fading away as the stethoscope approached the apex, the aortic or the pulmonary valve region.

4. Alvarez, J. A., and Herrmann, G. W.: Unusual Signs from an Expansive Chiari Network Along with Signs of a Syphilitic Aortic Regurgitation, Am. J. Syph. 15:532 (Oct.) 1931.

The urine was of normal specific gravity and contained a small amount of albumin and occasional granular casts. The blood showed sickle cells but nothing else of significance. Kolmer and Kline tests were negative. The complement fixation test for gonococcal infection was markedly positive. Urea nitrogen was 150 mg. per hundred cubic centimeters of blood, and creatinine 9.6 mg. per hundred cubic centimeters. An electrocardiogram showed normal axis, depressed S-T interval in leads 2 and 3, and apparent inversion of T₁. The eyegrounds showed sclerosed arteries, numerous areas of retinal degeneration, probably the result of old hemorrhages, and one or two recent hemorrhages in both fundi. A roentgenogram indicated moderate general enlargement of the heart and generalized increase in bronchovesicular markings throughout both lungs.

This was clearly a case of hypertensive cardiovascular disease with uremia and bronchopneumonia. The unusual murmur was difficult to explain and occasioned much discussion and difference of opinion. Its resemblance to the murmur described by

Right atrium partly cut away to show the network: S V C, superior vena cava; I V C, inferior vena cava; C S, coronary sinus; F O, fossa ovalis; T V, tricuspid valve.

Roger in 1897 as characteristic of an uncomplicated defect of the interventricular septum was very striking. The bruit de Roger is continuous, is heard along the left sternal border, best at the third interspace or at the left of the xiphoid cartilage, and is not transmitted. This similarity in location and in character led to the diagnosis of patency of the interventricular septum.

The pathologic diagnosis after autopsy was hypertensive cardiovascular disease with arterial nephrosclerosis, and lobular pneumonia as a terminal event. When the heart was opened a characteristic network of fibers was found in the right auricle with no septal or valvular defect.

The following description of the heart is given by Dr. T. M. Peery, who performed the autopsy:

The heart was greatly enlarged, weighing 575 Gm. Its epicardial surface was smooth and glistening. On section the myocardium of the left ventricle averaged about 1.6 cm. in thickness; that of the right ventricle about 2 to 4 mm. All the valves appeared normal. The aortic ring measured 7.3 cm. in circumference, the mitral 10 cm., the pulmonary 9 cm. and the

tricuspid 12 cm. In the right atrium was a network of fibers, the central portion of which lay free in the orifice of the inferior vena cava and the cavity of the atrium. The total length of the network varied from 5 to 8 cm. Its upper and anterior attachment extended in a more or less straight line, 3 cm. in length, from the right border of the superior vena cava, just below and behind the lower margin of the crista terminalis, downward along the right wall of the atrium to a point about 5 mm. above the entrance of the inferior vena cava. At its attachment to the atrial wall it was a fenestrated membrane, roughly triangular, with numerous large defects, from the apex of which, and from its inferior border, numerous slender bands arose, which branched and joined other bands in an irregular fashion. The opposite attachment of the network extended linearly from the right margin of the inferior vena cava, upward and to the left, following the limbus of the inferior vena cava for about 2.5 cm., and then crossed the open mouth of the coronary sinus, which in this case had no other valve protecting it. At its left margin the membrane was triangular, measuring 1 cm. at its base and about 6 mm. in height, and was not fenestrated. From the apex the fibers converged, branching and joining other branches as at the other attachment. The fibers arising from the upper end of the right line passed to the lower end of the left, and those from the lower end of the right to the upper end of the left, so that as the membrane was stretched it appeared to be slightly twisted on itself. At the center of the network it was composed of from five to eight intercommunicating fibers of about the thickness of a slender chorda tendinea, as shown in the accompanying illustration. The foramen ovale can be entered by a flat probe, although it was at such an angle and so well protected by flaps on both the right and left atrial surfaces that it was probably not functionally open. The interventricular septum was intact, although the membranous portion of the septum was thin and transparent. The ductus arteriosus was closed. No other congenital abnormality of the heart was noted. The coronary arteries were patent but showed small atheromatous plaques.

COMMENT

The only importance that has been attached to Chiari's network is the possibility of its affording a site for thrombus formation, which may become the source of a pulmonary embolus, as in the case reported by Ebbinghaus.⁵ No physical signs have been noted except by Alvarez and Herrmann. In the case reported here there was no abnormality of the heart other than a partial patency of the foramen ovale, which was functionally closed, and it is very improbable that the murmur which was heard could be produced by the foramen ovale under such conditions. In the absence of patency of the ductus arteriosus or of any other defect it seems reasonable to conclude that the continuous murmur heard actually was produced by the network. The similarity between the murmur in this case and the murmur described by Alvarez and Herrmann is very striking, and since the network was the only point of identity in the pathologic changes observed in the two cases the assumption that it produced the murmur in both would appear warranted. That no murmur was observed when the patient was under treatment in the surgical ward possibly may be explained by its limited area of distribution and its situation. In a routine examination to determine the presence of valvular defects it might easily be overlooked, as it was not heard at any of the valve areas. Furthermore, it varied in distinctness so that at times it was heard with difficulty. The resemblance of the murmur to the bruit de Roger is so close that the differentiation of the two would be difficult or impossible.

CONCLUSION

A continuous murmur occupying the site of the murmur reported here may be a sign of Chiari's network as well as of patency of the interventricular septum.

The Chemical Laboratory

IN THE JOURNAL, NOV. 6, 1937, THERE APPEARED, UNDER THE AUSPICES OF THE A. M. A. CHEMICAL LABORATORY, A NUMBER OF REPORTS DEALING WITH ELIXIR OF SULFANILAMIDE-MASSENGILL. TWO OF THESE WERE ENTITLED "PRELIMINARY REPORT OF TOXICITY STUDIES ON RATS, RABBITS AND DOGS (FOLLOWING INGESTION IN DIVIDED DOSES OF DIETHYLENE GLYCOL, ELIXIR OF SULFANILAMIDE-MASSENGILL AND 'SYNTHETIC' ELIXIR)," BY DR. E. M. K. GEILING, JULIUS M. COON AND DR. E. W. SCHOEFFEL, AND "PATHOLOGIC EFFECTS FOLLOWING THE INGESTION OF DIETHYLENE GLYCOL, ELIXIR OF SULFANILAMIDE-MASSENGILL, 'SYNTHETIC' ELIXIR OF SULFANILAMIDE AND SULFANILAMIDE ALONE" BY DR. PAUL R. CANNON. IN THE EARLY COMMUNICATIONS IT WAS STATED THAT DR. GEILING AND CANNON WOULD MAKE FURTHER STUDIES. THESE ARE REPRODUCED HEREWITH UNDER THE AUSPICES OF THE A. M. A. CHEMICAL LABORATORY.

PAUL NICHOLAS LEECH, Director,
A. M. A. Chemical Laboratory.

PATHOLOGIC EFFECTS OF ELIXIR OF SULFANILAMIDE (DIETHYLENE GLYCOL) POISONING

A CLINICAL AND EXPERIMENTAL CORRELATION: FINAL REPORT

PAUL R. CANNON, M.D.
CHICAGO

During the months of September and October 1937 at least seventy-six¹ human beings in various localities died as a result of poisoning by Elixir of Sulfanilamide-Massengill.² By analysis,³ the A. M. A. Chemical Laboratory found this preparation to be essentially a 10 per cent solution of sulfanilamide in about 72 per cent diethylene glycol, together with some coloring and flavoring agents. There were no contaminants such as mercury, the effects of which might have resembled the clinical symptoms produced by the elixir. Apparently the makers of this product were unaware of its possible toxicity and distributed it freely without having tested it adequately on animals. It had not been submitted to the Council on Pharmacy and Chemistry of the American Medical Association nor did the Food and Drug Administration of the United States Department of Agriculture know of its composition. Newspaper reports of deaths from this "new medicine" created consternation among many physicians who were using sulfanilamide. Hundreds of inquiries were received by the American Medical Association asking for information as to the nature of the causative agent and its possible antidote. To answer these pressing queries, experiments⁴ were immediately undertaken by us at the request of the A. M. A. Chemical Laboratory. The elixir, its active components (pure diethylene glycol and sulfanilamide) and a "synthetic" composite were tested separately on groups of animals. Rats, rabbits and dogs were given the various drugs three times

daily in graded doses. The experiments were devised with the object of developing conditions which might simulate those in the human cases.

REVIEW OF THE LITERATURE PRIOR TO THE "ELIXIR" EPISODE

There were in the literature reports dealing with the toxicity of diethylene glycol by Von Oettingen and Jirouch⁵ and by Haag and Ambrose.⁶ The first named authors studied the acute toxicity of the compound and noted hydropic degeneration of the kidney. Haag and Ambrose, in addition to observing the acute toxicity in rats, also studied the chronic effects of adding it to the drinking water. They found that concentrations of from 3 per cent to 10 per cent proved rapidly fatal. Lower concentrations (0.03 per cent to 1.0 per cent) did not significantly affect the growth of their animals, which were killed and examined after 100 days of observation; no liver or kidney damage was observed. No pathologic changes, apparently, were reported at autopsy on those dying of large doses of diethylene glycol. Although not directly stated in these papers, it would appear that Von Oettingen and Jirouch studied this compound from the point of view of its industrial hazard, and Haag and Ambrose appear to have investigated the compound with respect to its safety as a hygroscopic agent in cigarettes. The lack of more complete data concerning the chronic effects of diethylene glycol should have made it even more imperative that it should not have been used as a solvent in therapeutic preparations intended for repeated use in relatively large amounts until additional information concerning its chronic toxicity and fate in the animal body had been secured.

Barber⁷ in 1934 reported five deaths from poisoning in factory workers exposed to dioxane, the anhydride of diethylene glycol (diethylene dioxide). At autopsy extensive hemorrhagic nephritis and necrosis of the central part of the liver were observed. The absence of fatty change in the liver in the fatal cases is of particular interest, since such changes do occur with other known poisoning agents on the liver, such as alcohol and chloroform.

In 1935 de Navasquez⁸ reported tubular necrosis of the kidneys accompanied by hepatic changes due to experimental dioxane poisoning.

When the "elixir" episode occurred there were also no experiments recorded in the literature dealing with the chronic toxic effects of sulfanilamide. In fact, in a later detailed account of the toxicity of sulfanilamide in animals, Marshall, Cutting and Emerson⁹ stated: "Despite the widespread use of sulfanilamide in the treatment of certain bacterial infections, very scanty data are available concerning its toxicity for animals. Several observers have reported on its toxicity, using very limited numbers of animals." However, the available data indicate that sulfanilamide is relatively non-toxic for animals. Furthermore, under the experimental conditions recorded there were no marked renal and

From the Departments of Pharmacology and of Pathology, the University of Chicago.

The funds for the experimental work were supplied by the A. M. A. Chemical Laboratory and by a grant from the Committee on Therapeutic Research of the Council of Pharmacy and Chemistry of the American Medical Association.

1. Several sources indicate that the number of deaths was more than 100. The figure quoted here represents the number of confirmed deaths.

hepatic lesions produced by this drug. It may also be emphasized that extensive use in human beings indicate that, when properly employed, it is reasonably safe.

LITERATURE FOLLOWING THE EPISODE

Simultaneously with the publication of our studies on the toxicity of the elixir and its components, there

Fig. 1 (case 9).—Section of the kidney showing focal cortical infarction with peripheral hemorrhage. Reduced from a photomicrograph with a magnification of 16 diameters.

appeared two independent reports on the toxic effects of diethylene glycol. Kesten, Mulinos and Pomerantz¹⁰ reported that diethylene glycol administered to rats by mouth and to rabbits intravenously caused severe injury to the epithelium of the renal convoluted tubules, accompanied by anuria and uremic coma. The liver and adrenals were less regularly involved. Three per cent diethylene glycol (0.9 cc. per rat daily) in the drinking water killed about 50 per cent of the rats within two months; 5 per cent killed 25 per cent within a week. Rabbits were given single injections intravenously. Some animals died and others were killed at varying periods after injection. Significant pathologic lesions were observed in the kidneys of about half of the experimental animals. Holck¹¹ also reported experiments on rats given diethylene glycol in food and water. A 5 per cent solution of diethylene glycol in the drinking water killed his rats in about eight days, but the pathologic results were inconclusive.

ANIMAL EXPERIMENTS

Our toxicity experiments were undertaken on normal rats, rabbits and dogs. The animals had free access to food and water. In our experiments were used (1) pure diethylene glycol, (2) pure sulfanilamide, (3) Elixir of Sulfanilamide-Massengill and (4) "Synthetic" elixir of sulfanilamide compounded by the A. M. A. Chemical Laboratory with pure substances in approximately the same proportions as found in the Massengill elixir.

Appropriate chemical tests ruled out the possible presence of mercury and of impurities present in the Massengill preparations.

The animal experiments were devised (1) to determine the toxic and lethal doses of each of the substances when given in relatively small doses by stomach tube

three times a day. This information seemed particularly necessary since no data on this point were available in the literature; (2) to reproduce in healthy experimental animals in about the same period of time, the clinical and pathologic picture as presented in patients who had taken fatal doses of the Elixir of Sulfanilamide.

There is considerable species, as well as individual, variation in the toxicity of the drugs used under the conditions of our experiments. Rabbits were found to be the most sensitive experimental subjects. The doses used in our first experiments were larger than the amounts that proved fatal to the human beings, which were based on weight relationships. However, in later experiments carried out by Mr. A. Rodaniche on rabbits, doses comparable to the human doses proved fatal in about 30 per cent of the animals. This point is illustrated in table 1. These data are representative of more than fifty such experiments conducted over a similar range of dosages. The wide variations in susceptibility are evident from the table. Data with other species are published elsewhere.⁴

The course of the intoxication in the animals was noted frequently. A toxic syndrome⁴ developed which simulated closely the average clinical picture in the human fatal cases; this is described later. In rats, after about the fourth dose, the fur became ruffled, there was increased thirst and some diuresis, food was refused, urinary excretion later became scanty, and eventually complete anuria developed. The animals exhibited an

Fig. 2 (case 11).—Section of the kidney showing diffuse cortical infarction with recent hemorrhage. Reduced from a photomicrograph with a magnification of 17 diameters.

increased rate and depth of respiration and finally died in coma. Rabbits exhibited essentially the same picture but were more sensitive than rats. Dogs too behaved similarly, but the dosage could not be so accurately determined because of the tendency of the dogs to vomit after the administration of both diethylene glycol and the elixirs.

CONCLUSIONS FROM ANIMAL EXPERIMENTS

Based on more than 100 necropsies and a considerably larger number of experiments, the following summation and conclusions seem warranted:

1. Diethylene glycol was the chief toxic component of Elixir of Sulfanilamide-Massengill examined, because experimental animals given diethylene glycol alone exhibited essentially the same clinical course and pathologic changes in the kidney and liver¹² as did those treated with similar doses of Elixir of Sulfanilamide-Massengill or a "synthetic" elixir containing the ingredients in the same proportion as found by analysis in the Massengill preparation.

2. Sulfanilamide alone, if given in doses of 0.2 Gm. per kilogram three times a day, did not prove fatal to rats, rabbits or dogs after eight or more divided doses. However, when sulfanilamide was given in this dosage in the form of Elixir of Sulfanilamide-Massengill or in the "synthetic" elixir, either preparation was fatal to experimental animals and they presented a clinical and

Fig. 3 (case 2).—Section from the kidney. Note the extensive hydropic degeneration of tubular epithelium with obliteration of lumens, the normal glomerulus and the absence of leukocytic infiltration. Reduced from a photomicrograph with a magnification of 360 diameters.

pathologic picture closely resembling that reported for the human cases in which death occurred after ingestion of the Massengill elixir.

3. Although animals receiving sulfanilamide in doses of 0.2 Gm. per kilogram three times a day did not succumb, several of them had convulsions. Numerous animals were killed after having received eight or more divided doses of the drug. None of them had anuria, nor did they exhibit the renal and hepatic changes found in animals treated with either the Massengill or the "synthetic" elixir. While we do not believe that the sulfanilamide had any important part in the intoxications resulting from the elixir of sulfanilamide, one must not overlook the possible damage to tissues that may result when sulfanilamide is administered to experimental animals or to human beings with impaired renal function.¹³

4. The pathologic picture was essentially similar in the three species of animals, whether given the Elixir of Sulfanilamide-Massengill, the "synthetic" elixir of sulfanilamide or diethylene glycol alone. The pathologic

changes were those of a severe chemical nephrosis with intracellular edema of most of the epithelial cells of the convoluted tubules, resulting in tubular obstruction by compression and by the intraluminal formation of casts. This intracellular edema in the kidneys leads to internal disorientation of cells of the convoluted tubules and offers an explanation for the tubular obstruction.

Fig. 4 (case 9).—Section of the kidney showing the severe hydropic degeneration, the normal glomerulus and the absence of leukocytic infiltration. Reduced from a photomicrograph with a magnification of 225 diameters.

anuria, uremia and death. Whether this intracellular change is due to cellular anoxia, with consequent intracellular edema, necrosis and cellular desquamation, or whether it is due to hygroscopic properties of diethylene glycol is a question that must await further investigation.

These changes in the kidneys and liver were not due to sulfanilamide. With sulfanilamide, the microscopic changes were slight and consisted of moderate fatty degeneration in some of the collecting tubules in the dogs and to a lesser degree in the rats. The livers of both dogs and rats showed no hydropic degeneration and practically no fatty degeneration. There is but little question therefore that the severe chemical nephrosis

Fig. 5 (case 6).—Section of the kidney showing focal hydropic degeneration and obliteration of lumens. Reduced from a photomicrograph with a magnification of 360 diameters.

of the dogs, rats and rabbits is due to diethylene glycol alone. We cannot say, however, that under conditions of anuria, with retention of sulfanilamide in the blood stream, some tissue damage by sulfanilamide may not be added to that of diethylene glycol.

COMPOSITE CLINICAL PICTURE IN FATAL
HUMAN CASES

The following is a composite clinical picture observed in patients who died following the ingestion of variable amounts of Elixir of Sulfanilamide. The symptoms observed are taken from reports published by Homer A.

Fig. 6 (case 4).—Section showing hyaline casts in the lumens of the collecting tubules. Reduced from a photomicrograph with a magnification of 225 diameters.

Ruprecht and I. A. Nelson of Tulsa,¹⁴ by O. E. Hagebusch¹⁵ and by K. M. Lynch,¹⁶ and also from communications by physicians to Dr. Paul N. Leech, Secretary of the Council on Pharmacy and Chemistry of the American Medical Association, and from reports obtained by inspectors of the Federal Food and Drug Administration. The patients ranged in age from 11 months to 70 years; the dosage of Elixir of Sulfanilamide administered ranged from 1½ to 6 ounces (45 to 180 cc.).

The onset of symptoms was variable; in one instance the patient complained of symptoms immediately after the first dose. Patients usually complained first of a

Fig. 7 (case 11).—Section of the kidney showing hyaline necrosis of the blood vessel walls and hyaline thrombosis in the area of recent infarction of the cortex. Reduced from a photomicrograph with a magnification of 260 diameters.

sensation of "heartburn," followed by nausea, abdominal cramps, dizziness, malaise and vomiting, with diarrhea occasionally and later pain in the back over the region

of the kidney and in the abdomen. In fact, the condition was thought by some physicians to be an acute abdominal process and surgical intervention was recommended, although this was not carried out. These symptoms occurred about twenty-four hours after medication was started and were followed by oliguria and later anuria. The patients became drowsy and had slight puffiness of the face and slight jaundice in some instances. They became progressively comatose and died in from two to seven days after onset of anuria in uremic coma. The characteristic physical and clinical conditions were cutaneous pallor without cyanosis, slow and deep respirations and varying degrees of pulmonary edema, as manifested by rales throughout both lungs. There were subnormal temperatures and slow pulse, tenderness over the kidneys and upper part of the abdomen and edema of the dependent parts with ascites. The blood pressure was not significantly elevated. There was no anemia, but there was usually a moderate leukocytosis. The urine was scanty and contained four plus albumin, casts and occasional leukocytes.^{16a} The nonprotein nitrogen of the blood rose to as high as 200 mg. and the creatinine went up in some patients to 12 mg. per hundred cubic centimeters.

Fig. 8 (case 1).—Section of the kidney showing hyaline necrosis of the vascular walls of afferent glomerular vessels in a region of cortical infarction. Reduced from a photomicrograph with a magnification of 260 diameters.

It may also be stated in passing that there is considerable variation in responsiveness of patients to the elixir. At least 100 persons took doses of the elixir varying from 1 to 8 ounces (30 to 240 cc.) without serious effects, although some did complain of gastric disturbances.

PATHOLOGIC CHANGES IN HUMAN CASES

Of the seventy-six persons who died as a result of ingestion of Elixir of Sulfanilamide, we have been able to examine the tissues from fifteen, and this report deals particularly with twelve of these. The necropsy material was sent to us through the aid of or by federal inspectors of the Food and Drug Administration of the U. S. Department of Agriculture, by the secretary of the Council on Pharmacy and Chemistry of the American Medical Association and by several pathologists who performed the necropsies.¹⁷

16a. Similar changes are found in dogs poisoned with diethylene glycol (unpublished data).

17. The following pathologists, who were generous in their cooperation, supplied us with the material for the present study: Dr. Omer E. Hagebusch, St. Louis (cases 1, 2, 3, 4, 5); Dr. Ralph Monger, Knoxville, Tenn. (cases 6, 7); Dr. K. M. Lynch, Charleston, S. C. (cases 8, 9, 10); Dr. R. L. Thompson, St. Louis (case 11) and Dr. Paul Brindley, Galveston, Texas (case 12).

14. Ruprecht, H. A., and Nelson, I. A.: Clinical and Pathological Observations, J. A. M. A. 109:1537 (Nov. 6) 1937.

15. Hagebusch, O. E.: Necropsies of Four Patients Following Administration of Elixir of Sulfanilamide-Massengill, J. A. M. A. 109:1537 (Nov. 6) 1937.

16. Lynch, K. M.: Diethylene Glycol Poisoning in the Human, South. M. J. 31:134-137 (Feb.) 1938.

Table 2 is a brief and incomplete summary of the cases reviewed by us and includes the clinical diagnosis, amounts of elixir of sulfanilamide administered, the age of the patient and the like. Three of these have been reported elsewhere (cases 8, 9 and 10) and case 12 is to be reported by Drs. Brindley and Kelsey in a future issue of the *Texas State Journal of Medicine*. We shall attempt, therefore, only to summarize the necropsy results as given in the literature and as obtained from the necropsy protocols and material sent to us for study. Incompleteness of data is due to the fact that many of the necropsies were performed under unfavorable circumstances for weighing organs or because of limitation of permits for necropsy, but in all instances the liver and spleen were carefully examined grossly and microscopically.

In the original telegraphic report sent to the headquarters office of the American Medical Association on Oct. 15, 1937, by Drs. Homer A. Ruprecht and I. A. Nelson,¹⁴ describing the postmortem observations in five cases of poisoning by Elixir of Sulfanilamide at Tulsa, Okla., the following features were mentioned: a tawny but not enlarged liver; kidneys mottled and purple, in severe cases showing superficial cortical necrosis;

Fig. 9 (case 6).—Section of the 900 Gm. liver showing focal central hydropic degeneration of hepatic cells with absence of marked inflammatory reaction or of actual necrosis. Reduced from a photomicrograph with a magnification of 60 diameters.

pathologic changes in the other viscera insignificant, and inconstant accumulations of clear, straw-colored fluid in the peritoneal, pleural and pericardial cavities. Microscopic examination showed "a consistent hydropic tubular nephrosis with central degeneration of liver with cells showing foamy cytoplasm."

A few days later, Dr. O. E. Hagebusch¹⁵ reported to the A. M. A. headquarters the results of necropsies in four cases at East St. Louis, Ill., as follows: "pulmonary edema, marked nephritis with hemorrhage into the cortex of the kidney, marked hemorrhage into the pericardium, mucosa of the stomach and duodenum and into the serous surfaces of lung and liver. The liver is pale, edematous and enlarged." At about the same time two patients died in Memphis, Tenn., after ingestion of the elixir and the postmortem examinations by Dr. Harry C. Schmeisser, T. C. Moss and C. E. Gillespie revealed a similar picture. Finally, early in October, four persons died in Charleston, S. C., after ingestion of the elixir and necropsies by Dr. K. M. Lynch¹⁶ revealed the general observations just described.

All these observers recognized the unusual nature of the pathologic changes, and both Ruprecht and Nelson,

and Schmeisser, Moss and Gillespie noted their similarity to those of dioxane poisoning reported by Barber and de Navasquez. Subsequent studies have but served to emphasize the essentially identical pathologic effects in the kidneys and livers of human beings poisoned by Elixir of Sulfanilamide, and of animals given toxic

Fig. 10 (case 12).—Section of the 2,430 Gm. liver showing focal central hydropic degeneration of hepatic cells with absence of cellular disintegration. Note the shrunken pyknotic nuclei in the areas of hydropic degeneration. Reduced from a photomicrograph with a magnification of 60 diameters.

doses by mouth of either dioxane or diethylene glycol. There are apparently no known chemical substances other than these particular glycols which cause such a distinctive type of pathologic lesion in the liver and kidney.

The composite results of necropsy in these twelve cases may be summarized as follows: In several there was generalized edema (ascites, hydrothorax, hydropericardium and edema of the lungs) and, in some, recent hemorrhages into the gastrointestinal tract and lungs, evidences of increased capillary permeability.

Fig. 11 (dog 6).—Section of the kidney of a dog given 0.8 Gm. per kilogram of body weight of Elixir of Sulfanilamide-Massengill over a period of four days. It died with symptoms of loss of appetite, vomiting, rigidity of the hind legs, weakness, dyspnea, coma, opisthotonos, extensor rigidity of front legs and deviation of the head to the right. Note the diffuse hydropic degeneration of the epithelium of the convoluted tubules and the obliteration of the lumens, just as in the human fatal cases. Reduced from a photomicrograph with a magnification of 225 diameters.

presumably from the acidosis and uremia. Bronchopneumonia occurred in some patients but not in all. The principal pathologic changes were in the kidney and liver. The former was enlarged in all twelve cases and in one (case 12) weighed 500 Gm. In eight of the

twelve symmetrical cortical necrosis with recent hemorrhage, particularly at the corticomedullary border, was the conspicuous feature (figs. 1 and 2). These cortical infarcts were absent in the kidneys of one adult and in three children between the ages of 2 and 6 years. The kidneys were described as flabby, pale and swollen, and their surfaces bulged after sectioning.

Fig. 12 (dog 7).—Section of kidney of a dog given 2.3 cc. of diethylene glycol by mouth per kilogram of body weight, three times a day over a period of seven days. The dog died with symptoms of weakness, loss of appetite, vomiting and tremors. Note the hydropic degeneration of tubular epithelium in the convoluted tubules. Reduced from a photomicrograph with a magnification of 225 diameters.

Microscopic examination revealed an unusual type of chemical nephrosis, the characteristic lesion being a severe vacuolation of the epithelium of the convoluted tubules, the so-called hydropic degeneration (figs. 3, 4 and 5). These cells appear "ballooned," as if the cytoplasm of each cell were a bag of water and there were no cytoplasmic material left to take the stain. The nuclei in such cells are shrunken and pyknotic and are absent in some. This profound swelling leads to complete obliteration of the lumens, and the anuria and uremia are most reasonably explained on the basis of mechanical stoppage of the flow of urine. Actual necrosis is not conspicuous in such cells, although some contain granular eosinophilic material in the cytoplasm, and there is some nuclear disintegration. The general picture suggests a "water-logging" of the cells rather than an effect of an extremely toxic protoplasmic poison. In some kidneys the epithelium of the convoluted tubules looks collapsed, as if the hydropic cells had ruptured and had liberated their contents. Here the lumens were open but seemed to be functionless. In other kidneys the hydropic degeneration was less conspicuous in some areas and here the convoluted tubules were lined with flattened cells in which at times were mitotic figures or giant nuclei, indicating attempts at regeneration. The glomeruli, in general, were but little affected except as they participated in the vascular changes associated with the cortical necrosis. In these areas of recent infarction the blood vessels, both small arteries and veins, contained hyaline thrombi, and the walls of many exhibited hyaline necrosis (figs. 6, 7 and 8). The infarcted area was infiltrated and surrounded by accumulations of red blood cells, and the tubules showed the characteristic changes of coagulation necrosis. Leukocytes were infiltrating these areas, although not more so, apparently, than is usual in an area of infarction. The collecting tubules usually contained hyaline casts, erythrocytes and accumulations of

leukocytes. Fat stains showed practically no fatty degeneration in the areas of hydropic degeneration.

The mechanism of action of diethylene glycol as it passes through the kidney is still uncertain. In view of the fact that diethylene glycol is a hygroscopic agent, owing presumably to the two hydroxyl groups in its molecule, we suggested in our preliminary report that its presence within the epithelial cell might cause intracellular absorption and retention of water with consequent intracellular edema. Furthermore, because it is an ether, dihydroxy-diethyl ether, its solvent powers may cause injury to the cell membrane, followed by imbibition of water from the surrounding fluids. Evidence has been put forward¹⁸ that in the glycol group "only those containing one or more ether linkages cause hydropic degeneration of parenchymatous cells." The adverse effects in the kidneys, therefore, are apparently due more to the mechanical closure of the lumens from the swelling of the cells than to actual necrosis in its most severe aspects, although such a profound involvement of parenchymatous cells causes death of cells, particularly if the effect is intense or prolonged.

The circulatory changes leading to infarction, hyaline necrosis of blood vessel walls and thrombosis may be explained as secondary phenomena due to blood stasis and tissue anoxia following swelling of the kidney, although a direct toxic action of diethylene glycol cannot be excluded. It is interesting that the vascular changes have occurred mainly in human beings and to but a slight degree in the experimental animals. The similarity to the so-called symmetrical cortical necrosis of the kidneys is striking. Scriver and Oertel,¹⁹ in their discussion of this condition, have suggested that it is probably due to "vasoparalysis of terminal arterial segments with resulting blood stasis and segmentary thrombosis with proximal extensions" due to strong irritation of the vascular segments, an explanation in

Fig. 13 (dog 3).—Section of the kidney of a dog given 0.2 Gm. per kilogram of body weight of sulfanilamide by mouth three times a day. The dog was killed eight days later. Note the essentially normal convoluted tubules and glomeruli with no evidences of hydropic degeneration or other degenerative change as revealed by hematoxylin and eosin stain. Reduced from a photomicrograph with a magnification of 225 diameters.

harmony with the experiments of Ricker and his students.¹⁰ A similar effect may result from the action of diethylene glycol. De Navasquez²⁰ more recently has

concluded that the symmetrical cortical necrosis of the kidneys described by Barber⁷ in human cases of dioxane poisoning was histologically identical with cortical necrosis of pregnancy. He thought also that in both conditions the necrosis of the walls of the intralobular arteries and their efferent glomerular branches led to ischemia and necrosis of the parenchyma.

stains, however, showed practically no fat in these cells, fatty degeneration occurring only in the hepatic cells at the margins. The nuclei were shrunken and pyknotic but not disintegrating, as a rule, though in some there was nuclear fragmentation, indicating a moderate degree of actual necrosis. Inflammatory infiltrations of leukocytes were minimal, if present at all (figs. 9 and 10).

The livers were recorded as enlarged in all cases but one (case 6), in which it weighed only 900 Gm. The largest liver was found in case 12, in which it weighed 2,430 Gm. They were described as "tawny" or yellowish, although not bile stained, with pale, soft surfaces which bulged after sectioning. They presented the opposite picture of chronic passive congestion in that the centers of the lobules were light colored and the peripheries were darker. Microscopic examination revealed in all a central hydropic degeneration of the hepatic cells, with the cells "ballooned" and with the cytoplasm practically devoid of stainable material. Fat

The changes found in other organs were insignificant, other than congestion and hemorrhages of the stomach and intestine, which may have been a late effect of the uremia and terminal heart failure.

The similarity in dogs between the effects of diethylene glycol alone and of comparable amounts of Elixir of Sulfanilamide are shown in figures 11 and 12, where the extensive hydropic degeneration of epithelium of the proximal convoluted tubules is well seen. That the effect is not due to sulfanilamide alone is shown in figure 13, the reproduction of a photomicrograph from the kidney of a dog given twenty-one doses of sulfani-

amide by mouth, 0.2 Gm. per kilogram three times a day. The kidney is essentially normal so far as hematoxylin and eosin staining is a criterion. As a matter of fact, frozen sections and fat stains showed a moderate fatty degeneration of epithelium in the collecting tubules, most marked near the corticomedullary border but minimal in the tubules most affected by diethylene glycol.

COMMENT

The similarity between the clinical course and the pathologic picture of the fatal human cases and that observed by us in the experimental animals affords conclusive proof that the chief toxic agent in Elixir of Sulfanilamide was the diethylene glycol. We showed this substance to have a cumulative effect. Evidently the time interval between doses and the concentrations in which the elixir was recommended for human use exceeded the capacity of the body to handle the drug without producing serious injury.

Experiments are now in progress to determine the manner of excretion and the levels at which different species of animals can handle diethylene glycol.

We are permitted to state that Dr. Herbert O. Calvery, chief pharmacologist of the Food and Drug Administration, Washington, D. C., and his staff are conducting experiments which are in general accord with our own observations.

The fact that increasing numbers of new chemicals are being introduced into therapeutics serves to direct attention anew to the necessity of adequate toxicologic studies on such compounds which are to be used in medical practice. It is only by precautions of this sort that future tragedies similar to the elixir episode will be avoided. The new food and drug act is intended to prevent, so far as possible, the introduction of new remedies which have not been satisfactorily tested on experimental animals. It is unfortunate that, in the past, too many drugs have been introduced for use in human beings without adequate preliminary studies of their possible injurious effects, and in some instances drugs have been indiscriminately marketed without any preliminary knowledge of their toxic potentialities.

A satisfactory program of preliminary trials for a new drug was outlined by Leake²¹ in a discussion of drug policy presented before the Section on Pharmacology and Therapeutics of the American Medical Association at its annual session in 1929. It is interesting to note the clearness with which Leake anticipated the conditions responsible for the elixir episode as described in the government report.²² In his paper, he states, "many drug firms make the mistake of believing that their chemists can furnish trustworthy pharmacologic opinion. Indeed, some eminent chemists, impatient with careful pharmacologic technic, have ventured to estimate for themselves the clinical possibilities of their own synthetics. . . . There is no short cut from chemical laboratory to clinic, except one that passes too close to the morgue."

It is important to recognize that, in the examination of a drug with a view to its use in therapeutics, the following conditions are essential:

1. If at all possible, the exact composition (qualitative and quantitative) should be known; or, if not

obtainable, the detailed method of preparation of the product.

2. Acute toxicity studies on a sufficient number of laboratory animals of different species should be made; studies on one species alone may be very misleading.

3. Chronic toxicity experiments at varying dosage levels and with different species must be performed in order that any possible cumulative effect of the drug may be noted.

4. Careful and frequent observations of the animals are necessary, so that a composite picture of the clinical course is available. The data on many drugs are very deficient in this respect.

5. Careful pathologic examination of the tissues with appropriate stains is necessary.

6. Effects of the drug on animals with experimental lesions of various important excretory or detoxifying organs, especially of the kidneys and liver, should be studied.

7. The rate of absorption and elimination of the drug, its path and manner of excretion, and the concentration levels in the blood and tissues at varying times after administration must be determined.

8. The possible influence of the presence of certain foodstuffs or drugs should be noted. For example, magnesium sulfate should not be administered to a patient undergoing treatment with sulfanilamide.

9. Careful examinations for idiosyncrasies or untoward reactions should be made.

It is recognized that some will consider these safeguards to be too rigid and that they may simply be considered an ideal. It can correctly be charged, in fact, that some of the pharmacopeial drugs have not been studied along such lines. Admitting this, it is nevertheless regrettably true that many human lives have been sacrificed by the failure to meet the standards of these preliminary tests and that many more lives will be sacrificed if such standards are not put into effect. Any essential compromise with these requirements will inevitably exact a toll of deaths or injuries among the public. The life and safety of the individual should not be subordinated to the competitive system of drug exploitation.

The Elixir of Sulfanilamide catastrophe should once again serve as a warning to physicians who so readily prescribe unofficial drugs. There is no good reason why physicians should not have recourse to the simple expedient of prescribing only official or Council accepted preparations. By so doing they not only safeguard their patients but place their own influence solidly in favor of rationalized therapeutics. In addition, such a policy will tend to deemphasize the present enormous expenditures for advertising exploitation and tacitly direct drug manufacturers toward using their resources for the development of new and genuinely valuable agents in the treatment of disease. (Nonessential modifications of established drugs have no place in modern therapeutic practice.)

CONCLUSION

The intelligent, energetic and cooperative manner in which the representatives of the American Medical Association, of the Food and Drug Administration of the U. S. Department of Agriculture and of cooperating educational institutions worked brought this episode to a speedy solution. Had it not been for their splendid service the toll of human life would probably have amounted to several hundreds.

Special Article

VITAMIN B₁

METHODS OF ASSAY AND FOOD SOURCES

HAZEL E. MUNSELL, PH.D.

WASHINGTON, D. C.

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

The importance of vitamin B₁ in physiology and pathology has emphasized markedly the need of devising accurate methods for the quantitative determination of this substance in foods. Until recently the chemical identity of vitamin B₁ was unknown, rendering it impossible to develop chemical methods of analysis, and accordingly recourse was had to biologic methods of assay using rats and pigeons as test animals. Much information regarding the vitamin B₁ content of foods has been gained in this way, especially by the method in which the growth of rats was used as the measure of potency. This paper presents the technical aspects of various methods of bio-assay for vitamin B₁ from the point of view of quantitative interpretation of the results obtained and discusses briefly the chemical methods that are being developed. It concludes with an evaluation of foods as sources of the vitamin.

BIOLOGIC METHODS WITH PIGEONS

The first methods devised for the assay of vitamin B₁ were based on the prevention or cure of polyneuritis in pigeons.¹ There was also developed the weight maintenance method,² which involved the determination of the minimum amount of a substance required to maintain the weight of a standard bird on a polished rice diet. Because of many experimental difficulties, these methods are now used by only a limited number of investigators. The preventive method lacked specificity and the results were far too variable to admit of satisfactory quantitative analysis. The weight maintenance method raised the question of whether the antineuritic factor (vitamin B₁) and the growth factor were identical.³ Although the curative method has been used more extensively than the others, it has not proved to be more than fairly satisfactory owing to several major difficulties, such as irregularity of appearance of polyneuritis, the development of multiple deficiencies because of the inadequacy of the polished rice diet, development of nonspecific symptoms due to inanition, temporary and spontaneous remission of symptoms, failure of cures and variability in the time of response in different

birds. In this connection it is interesting to note that the prevention of polyneuritis in young chicks was recently suggested as a means of assaying for vitamin B₁.⁴

The methods referred to are described in the literature in more or less final form and it seems unnecessary to present them in detail here. However, certain results obtained with the pigeon curative technic, more especially those concerned with the derivation of quantitative values, are or may be paralleled in the rat curative method which is now under investigation by the Committee of Revision of the U. S. Pharmacopeia. It seems advisable, therefore, to review briefly the results obtained with the pigeon curative technic on the basis of their experience value.

In the procedure with the pigeon curative technic there seem to be several items directly influencing the results obtained. The magnitude of the response of the birds to test doses of vitamin B₁, for instance, is conditioned not only by the quantity of vitamin B₁ administered but also by such factors as the nature of the basal diet used, the duration of the initial depletion period and the duration of vitamin B₁ administration.⁵ The method of administration of crystalline vitamin B₁ also affects the results in that the response to doses administered by injection is greater than the response to doses of the same size given orally.⁶

Several methods have been used or suggested for expressing the results of the assays quantitatively. In the very early tests, attempts were made to assess values by determining the minimum quantity (minimum curative dose) of the substance required to cure induced symptoms of polyneuritis. This procedure did not prove to be satisfactory because in practice it was not possible to define "minimum curative dose."⁷ It soon became apparent also that the responses of different birds to like amounts of vitamin B₁ bearing material vary widely and that direct comparisons can be made only from successive tests with the same bird.

Further studies were then made to determine the relation between the size of the curative dose of vitamin B₁ administered and the duration of cure. Evidence was presented⁸ to show that there is a direct quantitative relation between the dose and the duration of cure, i. e., the number of days of protection after cure before the onset of the next attack. In the application of this finding to the comparison of results with different substances, an attempt was made to reduce them to a comparable basis by expressing the relative potencies in terms of day doses per gram of material.⁹ Values obtained from results with different dose levels of a given substance showed wide differences, however, and it was later concluded that this procedure is not a valid one.⁶ The reason for this becomes clear when it is

recognized that the relation of the duration of cure to weight of material given is not represented by a straight line.⁷ It has been shown, however, that it is possible to derive a curve of reference representing the relation of duration of cure to quantity of vitamin B₁ ingested that is valid for use in interpreting results obtained by the curative method.⁷

Other estimates from data obtained with the pigeon curative method have been made on the basis of percentage of birds cured⁷ and the degree of accuracy in these values was shown to be as great as in those computed on the basis of duration of cure.

The chief points to consider in judging the worth of a biologic method are its specificity, its precision and its sensitivity. In the curative method, precision is contingent on the determination of the length of the curative period, which in turn depends on the determination of the time of onset of the symptoms of polyneuritis. Even if the symptoms indicating the onset of polyneuritis could be exactly described, frequent periodic observation during the entire twenty-four hours of a recorded day would be necessary to ascertain the exact time of onset. In most laboratories such complete observations are not possible and the recorded time of onset of symptoms at the beginning and at the end of the curative period may be considerably in error. Thus the value given as the duration of the cure may involve an error in recorded time, as well as errors arising from the use of birds given the curative dose at different stages of development of polyneuritis.

The sensitivity of the test is also not so great as might be hoped for. A tenfold increase in vitamin B₁ intake apparently extends the curative period from the minimum of two or three days to only six or seven days. It seems justifiable to say, therefore, that the method is seriously lacking both in preciseness and in sensitivity.

Catatorulin Effect.—During the course of studies in which pigeons were used to determine the potency of vitamin B₁ concentrates, it was observed that the oxygen uptake of brain tissue from avitaminous pigeons increased on the addition of concentrates of vitamin B₁ in lactate solution.¹⁰ This was interpreted to be in the nature of a catalytic effect and the active factor was designated catatorulin although there was strong evidence that it was identical with vitamin B₁. A technic was devised whereby the effect of the vitamin B₁ containing substance on the oxygen uptake of excised pigeon's brain was used as an index of the quantity of vitamin B₁ present.¹¹ The curve relating the dose of vitamin B₁ (micrograms to 3 cc. of solution) to oxygen uptake (milligrams per gram hourly), although not a straight line, was a smooth curve similar to the one relating vitamin B₁ intake to growth in rats. The catatorulin test has been suggested as a most promising one for comparing the potencies of vitamin B₁ containing substances, although further study is required to perfect the method.⁶

BIOLOGIC METHODS WITH RATS

The Growth Test.—The use of growth in the rat as a means of detecting the presence of vitamin B₁ in

substances was suggested as early as 1918. The method developed by Sherman and Spohn¹² and more especially the basal diet worked out by them was generally used up to the time when it was shown that for normal growth the rat requires in addition to vitamin B₁ a heat stable fraction remaining in autoclaved yeast. The Sherman and Spohn basal diet was then modified by Chase¹³ to include sufficient autoclaved yeast so that vitamin B₁ was the first if not the only growth limiting factor.

The use of a preliminary depletion period was also suggested at this time as a precautionary measure even though it is generally agreed that vitamin B₁ is not stored in the body to any great extent and that animals given a vitamin B₁ free diet show only slight residual growth.

The procedure of the rat growth technic,¹⁴ like that of any other method, is carried out more or less according to the tenets of the investigator who is using it. For the purpose of this discussion, however, it does not seem necessary to consider in detail the various conclusions and recommendations that have been made except so far as they have a direct bearing on the uniformity and reliability of the results obtained.

Essentially, the procedure consists in the keeping of healthy young rats of known lineage and within a given age and weight range on a diet devoid of vitamin B₁ but adequate in all other factors needed for growth. They are maintained on this diet without supplement either for a specified length of time considered sufficient for depletion or until there are evidences that their stores of vitamin B₁ have been depleted. The animals are then given daily (or six times a week) weighed quantities of the material under investigation during a test period of specified length. The gain in weight during this period is used as a measure of the quantity of vitamin B₁ present.

The reliability of the results from the rat growth method depends in large part on the selection and grouping of the experimental animals. The quantity of the standard material fed should be that which gives a growth response at or near the critical level, this being the gain in weight from which comparisons are to be made. In the Sherman-Chase method, for instance, the point corresponding to an average gain of 3 Gm. a week is used. This point is located in the steepest part of the curve relating gain in weight to dose of vitamin B₁ but far enough up on the curve so that all the experimental animals may be expected to survive. It is often the practice to administer the test material at three or more dose levels and the Standard of Reference material at one or more dose levels. The quantities of test material are so selected that one induces a growth response at or near the critical level, one above this and one below.

The animals to be given the several doses must be as nearly alike as possible. On identical quantities of vitamin B₁ the growth response of males is usually

greater than that of females.¹⁵ Animals of different strain, or even litters of the same strain, may show differences in growth response for given quantities of vitamin B₁.¹⁶ For these reasons it is also recommended that the series of graded test doses and the dose of the standard be allotted to littermate animals of the same sex of about the same weight. Additional litters of animals are then used until the number of individuals on each dose level is sufficient to give an average result having an acceptable degree of reliability.

In the original Sherman and Spohn technic a test period of eight weeks was used. It was felt later, however, that results from a shorter period might more truly represent an uncomplicated vitamin B₁ effect, free from influence of other unknown growth essentials that might not have been supplied in the basal diet. Accordingly, a four weeks period was suggested.¹⁷ Results from a test period of two weeks have been reported to be very nearly as good as those from one of three weeks' duration.¹⁸ With a low rate of gain, results have been obtained on the basis of a ten day period,¹⁹ although a somewhat longer period than this would seem to be generally more satisfactory.

At the completion of the test the gains in weight for the individual animals in each group are determined and the average gains in weight for the different groups are calculated. If the test material contained vitamin B₁ the gains in weight will be graded to the dose. With crystalline vitamin B₁, for instance, growth has been shown to increase with doses as high as 160 micrograms per rat daily.²⁰

From the results obtained a curve (curve of response or dose-effect curve) is drawn, relating gain in weight to quantity of material given. The smoothness of this curve will serve as an indication of the reliability of the test. The quantity of test material estimated to give the same effect, i. e. to have the same potency as the quantity of standard fed, is then derived from the curve of response, which is drawn to a suitable scale so that the degree of precision implied by the value derived is in accord with the values used in constructing the curve.

The degree of accuracy of vitamin B₁ estimated by the rat growth method has been studied statistically and is reported to be high for a method of this type.¹⁸ The sensitivity also seems to be high, since it is possible to differentiate doses of crystalline vitamin B₁ differing in potency by only one microgram, although a dose of three micrograms must be administered before an appreciable growth response is obtained.²¹

Refecation and Coprophagy.—One of the more serious difficulties involved in the vitamin B₁ assay is that of eliminating the extraneous source of vitamin B₁ to which

the rat may have access as a result of "refecation."²² There is ample evidence for believing that vitamin B₁ may be formed in the cecum probably as the result of bacterial action on the food residues there.²³ Refecation appears to be dependent on the starch component of the diet. Raw potato starch, for instance, has a high refective power, while rice, wheat and rye starches are reported to have little or none.²⁴ Cooking the starch seems to destroy its refective property.²⁵ The vitamin B₁ due to refecation is not absorbed from the lower intestinal tract, but the rat may obtain benefit of it by the simple expedient of consuming his feces. The use of cages with large mesh screen bottoms tends to lessen this tendency but does not necessarily eliminate it altogether. One consoling feature with regard to refecation is that it does not occur in all cases and a watchful observer can generally identify refected animals by the bulky character of the feces and a growth response not in accord with the known intake of vitamin B₁.

The Curative Technic.—Polyneuritis in rats was reported as early as 1917 and in the following year a method for vitamin B₁ determination was described in which rats were kept on the vitamin B₁ free diet until they showed declining weight or symptoms of paralysis or both. Hofmeister²⁶ in 1922 was the first, however, to report the consistent appearance of polyneuritis in large numbers of rats. Several years later a comparison of results by the pigeon test and the rat curative test led to the conclusion that the same factor was measured with rats as with pigeons.⁹ About the same time Sandels,²⁷ using a basal diet containing adequate amounts of the heat stable components, reported that polyneuritis occurred in rats only when small quantities of vitamin B₁ were present in the basal diet. This point has since been corroborated by other investigators.²⁸

The first plausible plan for vitamin B₁ determination based on the curative technic with rats was that described by Smith.²⁹ Rats from 50 to 70 Gm. in weight and from 30 to 40 days of age developed symptoms of polyneuritis in from fifty to eighty days. Vitamin B₁ administered orally or by injection produced improvement in from three to five hours and a definitely curative effect in from eighteen to twenty-four hours. When the curative effect of a given dose had worn off the symptoms of polyneuritis recurred and were again alleviated

by a dose of the vitamin. It was suggested that the same animal might be used many times with little variation in its response to doses of equal potency. Although Smith found the curative effect proportional to the dose, the relationship was not considered quantitative and he made his comparisons, therefore, on the basis of the minimum curative dose. A cure lasting three days was considered the shortest remission period a minimum effective dose would bring about. The method was checked with a large number of substances and was considered to be entirely specific.

One particular advantage claimed for the foregoing method is the possibility of making comparative tests with the same animal, thus eliminating some of the errors due to differences in behavior of different test animals, a defect inherent in the rat-growth method. Several investigators working with the curative method have, however, reported considerable variation in the occurrence of polyneuritis and it is suggested that complete familiarity with the symptoms is essential before assay work is undertaken.³⁰ In this connection, criteria for judging the presence of polyneuritis have been described in detail and attention has been called to the fact that treatment of subsequent onsets may not always produce exactly the same result. The effect of such variation is reduced by the use of a sufficiently large number of animals.

To obtain greater uniformity in the occurrence of polyneuritis, the administration of known quantities of vitamin B₁ to each test animal has been recommended. Ammerman and Waterman,³¹ for instance, suggest the daily injection of 0.5 microgram of crystalline vitamin B₁. Dann³² uses a diet containing 400 Gm. of brewers' yeast per hundred pounds, which she claims gives a higher incidence of polyneuritis than the diets used by Ammerman and Waterman or Smith. Recent work³³ seems to indicate that the fat content of the diet may be an important factor in vitamin B₁ tests in relation to the production of polyneuritis in rats. A low incidence of polyneuritis was found among rats on a high fat diet, which is in accord with other observations on the fat-sparing action of vitamin B₁.

As already stated, studies for the purpose of selecting a suitable method for the assay of vitamin B₁ are at present being carried out under the direction of the Committee of Revision of the Pharmacopeia of the United States of America. Only the rat curative technic is being considered because a previous survey had indicated this to be the preferred method of the four procedures to which consideration had been given. Of the several modifications of the rat curative technic under investigation it seems necessary, however, to consider only the one in use at present in the Vitamin Division of the Food and Drug Administration of the United States Department of Agriculture.³⁴ This procedure is based on the one used by Smith, differing from it primarily in the use of a more adequate diet

consisting of sucrose 61.25 per cent, casein 18.0 per cent, salt mixture 1.40 per cent, autoclaved yeast 4.0 per cent, autoclaved peanuts 10.0 per cent, purified liver extract 0.75 per cent, and cod liver oil 2.0 per cent.

Sources of all known components of the vitamin B complex, including vitamin B₁ and factor W of Elvehjem, are presumably present in this diet. Special purification of the casein and the use of sucrose in place of starch are also new features. Although a known source of the minimal quantity of vitamin B₁ considered to be essential for the production of polyneuritis is not included in this diet, 100 per cent occurrence of polyneuritis in rats weighing from 40 to 70 Gm. is claimed for it. Furthermore it has been demonstrated that, with this diet, polyneuritis can be produced and cured repeatedly in the same animal, the production of ten or more such periods in a single animal being quite usual.

The details of the test may be summarized briefly. The basal diet is given to litters of rats from 12 to 13 days of age, which are kept with their mothers in cages having raised screen bottoms. The young are weaned when they weigh between 40 and 50 Gm. and are weighed weekly until the twenty-fifth day. At the end of this period they are put in individual cages, weighed daily and observed for symptoms of polyneuritis, which are classified as slight, acute or severe. Only animals in the acute stage are used in an assay.

When an animal is judged ready for the test, 2 international units of vitamin B₁ are administered and the weight and condition of the animal are again noted daily. The time elapsing between the administration of the curative dose and the recurrence of polyneuritic symptoms is designated the curative period. At the second occurrence of acute polyneuritis, a dose of the test material is given and the length of the curative period is recorded as before. In Kline's experience 2 international units of vitamin B₁ gives a curative period of from seven to eleven days with animals ranging in weight from 40 to 70 Gm. at the time the curative dose is administered.

Results obtained in the assay of crystalline vitamin B₁ by this method show that the duration of cure following administration of vitamin B₁ increases with increasing dosage. For a considerable range the relationship is linear, although at higher levels the curve flattens off as do other dose-effect curves showing the behavior of animals to graded doses of a given vitamin. In successive periods with the same animal the length of the curative period for a given dose of crystalline vitamin B₁ was found to be uniformly reproducible to a remarkable degree. Thus it was considered possible to use the length of the curative period as an accurate measure of the vitamin B₁ administered in a test dose. Errors due to variation of animals are eliminated by using the results of successive trials with the same animal to compare the potency of the test material with that of the standard.

In an assay performed in this way a given quantity of the test substance is considered to contain at least 2 international units of vitamin B₁ if it promotes in the experimental animals a total curative period (the sum of the days of the curative period of each of the animals) equal to or greater than the total curative period following the feeding of an amount of the international standard equivalent to 2 units. "If it is desired to determine the exact potency of an unknown [test material], it is preferable to feed it to a few animals at

various levels to determine the approximate quantity which contains two international units of vitamin B₁. The assay should then include successive feedings of the standard and unknown [test material] on at least eight animals." It is the opinion of the sponsor of this method that it is the most accurate procedure for vitamin B₁ determination that has been proposed.

Several measures other than duration of cure have been used for the quantitative expression of results from the rat curative technic. One of the first was weight recovery time,³⁰ i. e. the time required for the rat to return to the weight it showed when the injection of vitamin B₁ was made. Another measure used is the number of day doses per gram of material.⁹ This value is derived in the same way as in the method with pigeons and is therefore subject to the same limitations.³⁵ Reference has already been made to the minimum curative dose used in the method described by Smith.²⁹ Although this measure is more logical than the determination of day doses it involves the same difficulties associated with the determination of the minimum curative dose for pigeons.

The Bradycardia Method.—In 1929 a condition of heart block and bradycardia preceding appearance of symptoms of polyneuritis or head retraction was reported in pigeons fed polished rice. The following year a condition of bradycardia in rats was described³⁶ which did not seem to be due to lowered food intake but rather to the effects of lack of vitamin B complex, since the condition did not occur in controls on a restricted food intake. It was cured by administration of vitamin B₁. A special device for taking electrocardiograph records had been designed and the average normal heart rate for the rat was determined as from 500 to 530 per minute. Rats maintained on a vitamin B₁ free diet for about two weeks showed a gradual slowing of the heart rate, which finally reached a low level of 250-300 beats per minute. On the administration of vitamin B₁³⁷ the rate returned to normal and remained so for several days, when it began to fall again. The degree of recovery was "related" to the quantity of vitamin B₁ available.

Following this a method for the quantitative determination of vitamin B₁ based on the remission of bradycardia in rats was suggested.³⁸ In this method young rats weighing about 40 Gm. are given a vitamin B free diet and after about three weeks, or when loss of weight begins, electrocardiograms are taken. As soon as a heart rate of 350 beats per minute is recorded, the test sample is given and "dosing" is repeated until there is an increase in the rate. Thereafter, readings are taken every twenty-four hours until the heart rate has fallen again to the level recorded at the beginning. Both the increase in rate and the duration of the increased rate were found to be proportional to the dose administered. Cures of four days' duration are considered most satisfactory. Tests are made at several levels with from four to six animals at each level and a dose-effect curve is plotted. Comparisons are made to determine the quantities of the international standard that give the

same effect. An activated clay product, yeast, marmite and wheat germ, were assayed by the procedure described and also by the rat curative method, the rat growth method and the pigeon technic. The results by all four procedures agreed.³⁸

The advantages claimed for the bradycardia method are a short preparatory period, ease and rapidity in obtaining results, and economy in test animals since one animal may be used for several tests. The sensitivity is considered to be only slightly less than that of the growth method. The investigators admit that the chief drawback to the general use of this method is the expense of the electrocardiograph. It has been used by Baker and Wright³⁹ for the assay of about a hundred different foods. With 20 and 30 mg. of the International Standard of Reference, the method was considered accurate to within ± 20 per cent. Cures giving responses of about 450 beats per minute tended to be prolonged or irregular. The responses to the first test doses tended to be abnormal and these results, therefore, were discarded. The values reported by these investigators are in general somewhat higher than values given for similar products by other investigators.

The original proponents of this method have made a thorough study of it in a determination of the potency of crystalline vitamin B₁ preparations and have also used it extensively and apparently successfully in studies of the urinary excretion of vitamin B₁.⁴⁰ In the hands of others, however, it has not fared so well. Robertson and Doyle,⁴¹ who attempted to use it in the assay of a crystalline vitamin B₁ preparation, observed considerable fluctuation in individual animals. A single tracing, for instance, showed a rate in one part that was forty beats per minute higher than the rate in another part, and two tracings from one rat showed differences of 100 beats per minute. Another rat on a curative dose of 6 micrograms showed rates varying from 326 to 480. R. S. Harris,⁴² working with a cardiograph designed for the purpose, has found discrepancies of even greater magnitude in normal and in vitamin B₁ deficient rats.

QUANTITATIVE INTERPRETATION OF RESULTS BY THE BIOLOGIC METHODS

The variety of assay procedures described naturally makes one query concerning the quantitative interpretation of results. Those obtained in the early studies in which pigeons were used were interpreted either directly in terms of the curative dose, as already explained, or in relation to the potency of some other substance such as yeast assigned an arbitrary value, for example 1, 10 or 100. These data are difficult, if not impossible, to reconcile with values obtained by other methods and at most have little more than qualitative significance. It is probably safe to say that many of the data on the occurrence of vitamin B₁ obtained by the pigeon technic prior to the time of adoption of the international stand-

ards have not been quantitatively evaluated. This may in part account for the dearth of tabulated vitamin B₁ values.

Two units other than the international unit have been defined for the interpretation of data by the rat growth method. The first was the maintenance unit, which was defined⁴³ as that amount of vitamin B₁ which, when fed as a daily allowance, results in net maintenance of a standard rat over an eight weeks period under the conditions described. Although this unit was never used extensively and there are few data reported in terms of it, Cowgill has referred to it in his discussion of equivalents and for this reason it seems advisable to mention it here.

The large majority of values for the vitamin B₁ content of foods as well as for other substances has been expressed in terms of the growth unit. This is defined⁴⁴ as that amount of vitamin B₁ which, when fed daily under experimental conditions as described, induces in a standard test animal an average gain of 3 Gm. a week during the test period. Values expressed in this unit have been derived from results obtained with the Sherman-Spohn diet as well as the Sherman-Chase basal diet. The Sherman-Spohn diet did not contain a supply of vitamin G sufficient for growth, and values obtained with this diet therefore may or may not indicate the full vitamin B₁ value of the substance tested, depending on whether the basal diet and the test substance supplied sufficient vitamin G for growth. Roscoe⁴⁵ used a somewhat higher rate of gain, from 10 to 12 Gm. a week, for the growth unit.

The introduction of the international standards has given a more precise method of expressing vitamin values than was possible before these standards became available. There is evidence, however, that estimates made in terms of international units are not always as precise as they might have been. The derivation of values by the use of standards of reference by any method of analysis involves the determination of quantities of standard and of test material that give the same effect. The accuracy of the assay depends on the closeness of this determination. Many investigators use the method of trial tests to determine the quantity of test material equivalent to a given quantity of standard. With the wide variations inherent in results obtained by biologic methods a close match is obtained only if great care is taken in carrying out the assay; and, even when such results seem to have been obtained, the reliability is even more difficult to check. A perusal of published data indicates that in this procedure more attention should be given to the adoption of criteria for determining the limits within which the two effects may be considered to be identical. Other investigators may use a dose effect curve, as described under the growth method with rats, from which the quantity of test material equivalent to the quantity of standard used may be estimated if the results of the assay do not give it directly. Such curves may involve large errors of estimate, however, unless consideration is given to factors giving rise to variation in results with different test subjects.

The recently completed assay of the crystalline vitamin B₁ hydrochloride proposed for international standard to replace the adsorbate now in use indicates that vitamin B₁ values for substances assayed against the international standard adsorbate vary according to the method of assay used. Values obtained by the curative technics, for instance, were considerably higher than values by the prophylactic or growth method. It is suggested that in sick animals such as those used in the curative method there is incomplete elution of vitamin B₁ from the adsorbate in the alimentary canal. It has been shown⁴⁶ that rats seriously depleted of vitamin B₁ cannot fully utilize the vitamin B₁ present in preparations such as fullers' earth adsorbates. In the curative method, therefore, the response to the international standard adsorbate does not represent the full vitamin B₁ activity of the dose given and the vitamin B₁ potency of the test substance determined by this method is accordingly judged to be higher than it really is. In the growth method, on the other hand, the animals are healthy and seem to utilize fully the vitamin B₁ of the standard adsorbate. Vitamin B₁ values by the growth method are therefore probably more nearly true values although considerably lower than those obtained by the curative technics.

Whether this same relationship holds for natural products depends on the availability of vitamin B₁ in these products.

Since the adoption of the international standards, attempts have been made to derive a factor for converting vitamin B₁ values expressed in Sherman units to equivalent values in international units. Values from 1 to 4 Sherman units equivalent to 1 international unit have been suggested. As explained in an earlier paper of this series,⁴⁷ the growth units have no fixed value in terms of the vitamin for which they are defined and therefore conversion factors cannot be derived accurately.

Many food products present a difficulty in vitamin B₁ assays not experienced so generally in the case of other vitamins. Although vitamin B₁ occurs in a wide variety of foods, the quantity present in most cases is small. This means that the test doses used in the biologic assays must be rather large and it is often difficult, if not well nigh impossible, to get the animals to consume enough of the allotted portions to make the test reliable. Furthermore, it may not be possible to obtain responses that are divergent enough to indicate the dose effect relation essential to the derivation of a true estimate of the potency of the test material.

The foregoing discussion is intended to imply that vitamin B₁ values that have been reported, especially those of unusual magnitude, should not be accepted categorically apart from a consideration of the method of assay used and the exactitude with which the values were derived from the results obtained. When using tabulated values expressed in international units it is advisable to scrutinize them carefully to ascertain whether they were determined experimentally in international units or were derived by the use of a conversion factor from values determined in terms of some other unit.

CHEMICAL METHODS OF ANALYSIS

Although several chemical methods of analysis have been suggested for the determination of vitamin B₁, the thiochrome method is the only one that has been studied to any great extent. Early in 1935 Peters⁴⁸ reported that the purest preparations of vitamin B₁ available were converted by oxidation in aqueous solution into substances showing intense sky-blue fluorescence. Somewhat later, Barger, Bergel and Todd⁴⁹ succeeded in transforming vitamin B₁ into a pale yellow sulfur-containing compound by oxidizing it in alkaline solution with potassium ferricyanide. The compound formed showed an intense blue fluorescence in neutral or alkaline solution and had all the properties of the thiochrome described by Kuhn and his associates.⁵⁰ Jansen⁵¹ studied the quantitative transformation of thiamin to thiochrome and concluded that the reaction took place at an optimal p_H of 10 and the maximum reaction in one or two minutes. Excess potassium ferricyanide seemed to destroy the thiochrome. The thiochrome was then extracted with isobutanol and the extract transferred to a Cohen fluorimeter. The test with the international standard was made by eluting the vitamin with a mixture of alkali and potassium ferricyanide. The procedure of alkali extraction was later adopted for removing the vitamin from other materials. Westenbrink and Goudsmit⁵² applied the method of Jansen to the determination of vitamin B₁ in urine samples. The urine was diluted with three volumes of water and the reaction was carried out in an atmosphere of nitrogen. Errors due to interfering fluorescent substances were eliminated by "subtracting the fluorescence of a franconite eluate to which no potassium ferricyanide had been added from the fluorescence of some eluates which had been treated with different amounts of this oxidizing agent." Results by this technique agreed well with those obtained by Harris and Leong using the bradycardia method. Pyke⁵³ made a rather extensive study of the method as applied to the determination of vitamin B₁ in foods. The report covering this study gives a detailed description of the procedure, in which fluorescence was measured by a Cohen fluorimeter. Compensation for variation in intensity of the fluorimeter was obtained by reading the deflexion given by 10 cc. of solution containing 0.81 mg. of quinine sulfate in 100 cc. of tenth normal sulfuric acid. Readings from solutions of thiochrome were calculated back on the basis of 100 for this deflection. With the pure vitamin the fluorimeter readings and the concentrations of vitamin showed a straight line relationship. In the procedure as finally adopted the fluorescence given by a solution to which no potassium ferricyanide had been added was subtracted from the fluorescence of the treated solution to get that due to thiochrome.

Karrer and Kubli⁵⁴ also give a detailed description of the thiochrome reaction. These investigators feel that the violet fluorescence of thiochrome can be estimated more advantageously by the eye than by a photoelectric fluorimeter. Hennessy and Cerecedo⁵⁵ report success in the elimination of nonspecific fluorescence by employing synthetic zeolites for absorbing the vitamin.

Several other tests suggested for vitamin B₁ also depend on the formation of colored compounds. Prebluda and McCollum⁵⁶ described a purplish red compound formed with vitamin B₁ and *p*-amino acetanilid or methyl-*p*-amino phenyl ketone treated with nitrous acid which was stable and highly insoluble in water. Naimans⁵⁷ found that with vitamin B₁ containing substances bismuth potassium iodide gives an orange red precipitate which can be filtered, dried and weighed. This reaction is specific for the thiazole nucleus and the weight of the precipitate is proportional to the quantity of vitamin B₁ present.

In 1926 Jansen and Donath claimed a strong Pauly reaction (red color when treated with diazotized sulfanilic acid in the presence of sodium carbonate) for crystalline preparations of vitamin B₁. This reaction was studied by Kinnersley and Peters,⁵⁸ who found that it was stabilized by the addition of formaldehyde. These investigators felt, however, that the specificity of the reaction needed further proof.

FOOD SOURCES

Vitamin B₁ has been shown to be present in a wide variety of foods, but there are few foods of plant or of animal origin that may be considered potent sources of this factor. In planning adequate diets, therefore, it is necessary to depend on several food items to furnish the day's supply of vitamin B₁. This is in direct contrast to experience with vitamin A and vitamin C, in which a single food may furnish the major portion of the requirement for the day. The problem of planning for vitamin B₁ is further complicated by the fact that it is desirable to insure an adequate supply in the diet each day, since vitamin B₁ is not stored in the body to any great extent. These considerations become more significant when viewed in the light of the current tendency to give more attention to the subacute and chronic forms of the deficiency diseases.

At the present time dietary calculations for vitamin B₁ are made difficult by the dearth of data on the occurrence of this factor in foods, as well as by the further fact that values expressed in terms of the rat growth unit still comprise the major portion of those available. It is to be hoped that the development of new methods of assay that are more specific and more precise will furnish the incentive for more extensive studies giving values in international units. Tables of numerical values are given in several textbooks, and a summary of data that appeared in the literature up to January 1936 will be found in a publication recently issued by the United States Department of Agriculture.⁵⁹ It seems

unnecessary, therefore, to consider here more than the general aspects of food sources of vitamin B₁ with particular reference to the precautionary measures essential to insure against unnecessary losses during manipulative procedures, such as cooking or canning.

Vegetables, including potatoes, may be regarded as forming one of the more important groups to be depended on regularly for vitamin B₁. Exclusive of legumes they may be considered for general purposes on a par with one another, since they do not show differences among themselves that make it feasible to group them for relative B₁ content on the basis of any particular physical characteristic such as color, for instance. Although fruits may be rated as only fair sources of vitamin B₁, they are important in that they are generally eaten raw and in relatively large quantities, if used at all.

Vitamin B₁ tends to be concentrated in the germ portion and outer or bran layer of seeds. Legumes, nuts and whole grains are among the good food sources. Refined cereals and flours, however, contain very little of the vitamin because the germ and the bran layer are largely removed during the refining process.

Eggs, muscle meats and, more especially, the organ meats are rated as good sources. These products are not subject to variation due to changes in the vitamin B₁ content of the diet of the animals from which they are derived, as is the case with vitamin A. Certain muscle meats, specifically chicken and pork, have been described as rather unusual sources when compared with other similar products. Whether this is actually the case or only an accident of assay should perhaps be left for further investigation.

Milk becomes an important source of vitamin B₁ when considered on the basis of the quantity usually consumed and the fact that it may be used without treatment that would tend to lessen its potency.

The foregoing statements should be taken as applying to untreated or fresh forms of the products described. They do not cover foods that have been subjected to any of the various manipulative procedures concerned in preserving the food or preparing it for consumption. Vitamin B₁ is inactivated by heat in the presence of moisture, but in foods at least it is not readily destroyed through oxidation.

The actual loss of vitamin B₁ during the heat treatment of food may or may not be significant, depending on the conditions that prevail. Under most conditions inactivation occurs gradually as the time or temperature, or both, of heating increases. For general purposes this need not be considered significant up to one hour at 100 C. The acidity (or alkalinity) of the medium, however, has a significant influence on the rate of destruction, since inactivation increases with decreasing acidity, especially at temperatures above the boiling point of water. Inactivation of vitamin B₁ in milk powder during dry heating in air at 100 C. for as long as forty-eight hours has been reported as small. Recent experience⁶⁰ indicates, however, that losses in foods under conditions comparable to those in baking may be as high as 50 per cent.

Although vitamin B₁ is not readily destroyed at the temperature of boiling water, the greatest loss due to cooking may take place in foods that are boiled. Vita-

min B₁ is very soluble in water and it is easily conceivable that a large proportion of the vitamin may go into solution in the cooking water and be lost. Unless this liquid is served in some way to the person eating the food, the food itself should be held a questionable source of vitamin B₁, even though in the untreated form it is rated as a good source. This illustrates a cardinal point that unfortunately is often overlooked, namely that it is not the inclusion of a food item in the diet that is important but its actual nutritive value when consumed.

During canning of foods there is probably little loss of vitamin B₁ due to processing per se. Any loss noted in such products probably took place during the preparation of the food prior to the time it was put in the can. The full vitamin B₁ value of canned products is obtained only if no portion of the contents is discarded.

Too few data are available on the effect of storage on the vitamin B₁ in foods to admit of any definite generalization in this regard. There is little reason for believing, however, that there is any significant loss of vitamin B₁ under storage conditions that preserve the food satisfactorily for consumption. Information on the effect of drying is also scanty. The foods that have been assayed in the dried state were, for the most part, dried to reduce the bulk of the sample so that the experimental animal would consume the portion allotted. The material was dried under conditions assumed to effect no loss of vitamin B₁. This was only an assumption, however, since check tests could not be made on comparable samples of the fresh product. Results of assays carried out in this way have little significance, therefore, in relation to the vitamin B₁ content of the fresh product. Milk may be cited as an exception, since studies designed to determine losses of vitamin B₁ during procedures used to reduce the water content have been made on comparable samples of the fresh and dehydrated or partially dehydrated product. Losses during evaporation and drying were shown to be small.

Freezing seems to be a satisfactory method of preserving the maximum nutritive value of foods and there is reason to believe that vitamin B₁ is preserved in stored frozen foods, as well as are the other vitamins. When frozen foods are cooked, it is essential to remember that the vitamin may be more easily extracted from these than it is from the fresh product, and that care must be taken to serve all expressed juices.

Although it is permissible to claim that the ordinary diet may easily contain adequate supplies of vitamin B₁, it seems advisable to suggest that there is an almost equal opportunity for it to be low in this factor. The tendency to replace whole grain products by refined cereals and flour may entirely eliminate this important source for many individuals. Vegetables are often cooked with little or no regard for loss of vitamin B₁ value or, for that matter, nutrients of any sort. These two indiscretions alone eliminate two of the chief sources of this vitamin. Fruits, meat, milk and eggs, which constitute good sources of vitamin B₁, are among the high cost foods and are the first to be omitted in the low cost diet. With these considerations in mind it would seem to be expedient to give more attention to the vitamin B₁ supply especially in certain types of diets and to the possible ill effects that may result from the long-continued use of a diet low in this nutritionally important factor.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

ILLE PORTABLE UNDERWATER THERAPY TANK ACCEPTABLE

Manufacturer: Ille Electric Corporation, 386 Fourth Avenue, New York.

The Ille Portable Underwater Therapy Tank with Hydro-Massage is essentially a portable whirlpool bath recommended for heat treatment of legs and arms. It is designed for use in hospitals or offices. The complete equipment includes an extra wide stainless steel tank with an adjustable canvas seat, turbine agitator, immersion heater with dial thermometer and pump, all electrically operated, and filling hose, an arm rest, and optional metal chair on high frame for use in leg treatments. The tank rests on a heavy metal base mounted on four solid rubber casters for ease in moving from place to place. Total shipping weight is approximately 350 pounds or 325 pounds without chair. Inside dimensions are 28 inches high by 16 inches wide by 36 inches long. It operates on alternating current. Special equipment is required for direct current.

Ille Portable Underwater Therapy Tank.

It is filled with water by means of a hose which fits over any available standard faucet. Once filled, the tub may be trundled wherever the operator desires. The water is agitated and aerated by an electric turbine type of pump. The water is maintained at the desired temperature level by the immersion heater (1,000 watt consumption). The dial thermometer permits continuous reading of the temperature.

The agitator produces a gentle hydromassage, which is applied most effectively by placing the underwater jet next to the affected part. A gear device and crank enable the operator to move the agitator up and down within the tub and to increase or decrease the velocity of the ejection. The motor driven agitator may be attached to a full size tank large enough to permit the patient to lie at full length. Such tanks may be purchased from the manufacturer.

There is an electric pump for draining the tank. A valve connected to the lower part of the drain pipe permits complete drainage of residue.

This unit was investigated clinically and found to produce therapeutic effects not unlike those produced by other whirlpool baths. Mechanically it appears to be a well made piece of equipment.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Ille Portable Underwater Therapy Tank for inclusion in its list of accepted apparatus.

ADLANCO W-73 TWO-TUBE ULTRATHERM NOT ACCEPTABLE

Manufacturer: Adlanco X-Ray Corporation, 54 Lafayette Street, New York.

The Adlanco W-73 Ultratherm is intended solely for medical use. It is similar to the Council accepted Model G Ultratherm (THE JOURNAL, Nov. 14, 1936, p. 1636) except for a certain difference in wiring owing to the use of two tubes in place of one. The cabinet model may be procured with a walnut finish or a white painted exterior. Glass insulated electrodes are attached to the machine by rigid electrode arms with movable joints.

The unit contains two vacuum tubes, rated at 250 watts each. Its circuit is of the push-pull type. There are two transformers—one high tension, supplying current to the anodes, and one low tension, supplying current to the filaments of the tubes. The high tension current is controlled by a five step switch.

The filament current is controlled by a three step switch, supplying power with a voltage subject to local variations.

The output was measured by a lamp load, photoelectric cell and wattmeter. Six carbon filament lamps, each with 100 watt capacity, were connected in parallel and the maximum power output was determined to be 495 watts. The line electromotive force was 111 volts. Input power under these conditions was 1,460 watts.

The transformer temperature rise, taken after a two hour run at full load, was within the limits of safety. Burns may be procured with this unit but may be avoided by employing ordinary precautions. Provision has been made to eliminate radio interference by insertion of line filters.

The unit was investigated in a clinic acceptable to the Council and rendered satisfactory service. It appears to be as efficient as the average device of this type. No evidence was submitted by the firm to substantiate the efficacy of the unit in heating the deep muscle tissues of the living human thigh, although such information was requested and ample time given to obtain these data.

Since the firm has not fulfilled the requirements for acceptance and has circulated advertising matter which contains misleading, unwarranted or exaggerated statements, the Council voted not to accept the Adlanco W-73 Two-Tube Ultratherm for inclusion in its list of accepted devices. However, the Council will give the unit reconsideration without prejudice when the requirements and the Official Rules have been met.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

MRS. PALEY'S BABY FOOD—STRAINED GREEN BEANS

Manufacturer.—Paley-Sachs Food Company, Houston, Texas.

Description.—Canned, cooked sieved beans slightly seasoned with salt.

Manufacture.—Fresh green beans are thoroughly washed, trimmed, pressure cooked, sieved, filled into glass jars, vacuum sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 92.2%, total solids 7.7%, ash 0.5%, fat (ether extract) 1.1%, protein (N \times 6.25) 1.4%, reducing sugars as dextrose 1.4%, crude fiber 0.5%, total carbohydrates other than crude fiber (by difference) 4.4%, calcium (Ca) 0.040%, phosphorus (P) 0.028%, iron (Fe) 0.002%.

Calories.—0.3 per gram; 9 per ounce.

NUTRADIET BRAND UNDILUTED GRAPEFRUIT JUICE

Distributor.—The Nutradiet Company, a subsidiary of S & W Fine Foods, Inc., San Francisco.

Description.—Canned Florida grapefruit juice packed without added sugar.

Manufacture.—Tree-ripened grapefruit is mechanically cleaned and washed, cut in halves and reamed. The juice is strained, automatically filled into cans, vacuum sealed and processed at 71 C. for five minutes.

Analysis (submitted by manufacturer).—Moisture 87.7%, total solids 12.3%, ash 0.4%, fat (ether extract) 0.06%, protein (N \times 6.25) 0.6%, crude fiber 0.03%, carbohydrates other than crude fiber (by difference) 9.5%, titratable acidity as citric acid 1.7%, vitamin C (dye titration) 0.48 mg. per gram.

Calories.—0.41 per gram; 12 per ounce.

l'itamins.—Approximately 275 international units of vitamin C per ounce.

Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, SEPTEMBER 3, 1938

SPECIAL SESSION OF THE HOUSE OF DELEGATES TO CONSIDER NATIONAL HEALTH PROGRAM

The House of Delegates is the only body authorized under the Constitution and By-Laws of the American Medical Association to establish policies for the organization. Contrary to general belief, neither the Board of Trustees, the president nor any of the other officers or employees of the Association can establish a policy or point of view for the Association. It is their duty, once policies have been established by the House of Delegates, to promote and enforce them.

Ordinarily the House of Delegates meets once each year at the time of the annual session; the policies there promulgated become effective and remain effective until changed at a later session. To maintain the flexibility of the organization, however, the By-Laws provide that a special session of the House of Delegates may be held in response to a call issued by the speaker of the House whenever a sufficient number of members of the House of Delegates or of the Board of Trustees deem such a special session necessary. Some years ago when the Social Security Act was under consideration a special session of the House of Delegates was called to consider the part to be played by the American medical profession in this legislation. Now the Association is confronted with a national health program of tremendous scope and with the statement that it is the intention of the federal administration to make this program effective by legislation to be introduced at the next session of the Congress.

The Board of Trustees, having given this matter serious consideration, determined to request the speaker of the House of Delegates, Dr. H. H. Shoulders, to issue a call for the convening of a special session of the House of Delegates for this purpose. This call has been issued and the meeting will take place in Chicago on

September 16. According to the announcement of the speaker:

The business to be transacted at this special session shall be limited to the consideration of the national health program submitted to the National Health Conference recently held in Washington and to such other matters as may be submitted to the House of Delegates by the Board of Trustees.

The American Medical Association is among the most democratic organizations in the world today. Members of the House of Delegates are chosen by the houses of delegates of the individual state and territorial medical societies and these, in turn, are composed of delegates sent by the individual county medical societies. Such policies as the House may establish will become the official policies of the Association, to be urged on the medical profession, on the government and on the public generally as the House of Delegates may direct. Members of the American Medical Association will do well to follow closely the deliberations of this special session. Once the House of Delegates has spoken, its actions should be supported by the united voice of American medicine, so that it may be heard with respect and consideration when legislation comes before the Congress of our country.

THE EXPANDING INTEREST IN INDUSTRIAL HEALTH

Industrial health as a field of special medical interest is young. Its origin, first strivings and subsequent development are well within the memory of many physicians today. Indeed, many pioneers who early foresaw the notable contributions which medicine could make toward improving the physical and environmental welfare of American industrial employees are active today. Except by a devoted few, little serious attention was given to safe and healthful practices in industry thirty years ago. Few physicians realized the preventable character of most occupational disorders. By 1910, however, the preliminary investigations of the principle of compensation for industrial injuries had prepared the way for implementing the recommendations of the fact-finding commissions. The subsequent rapid and widespread adoption of compensation legislation by the states began to exert a profound influence on medical thought and practice. The forward-looking element in industry and in the medical profession recognized that a health and safety program, as adequate as possible within the limits of time and available personnel, was a necessity not from motives of altruism but as sound business practice.

Demands on the medical profession in the field of industrial health have continued increasingly. The interest which was formerly concentrated on traumatic and reconstructive surgery has expanded immeasurably.

At present there is scarcely a field of medical practice which has not been affected by problems of industrial health or has not contributed toward their solution. The strictly preventive medical aspects have long been preeminent in the scientific attack on occupational hazards. The achievements of the Division of Industrial Hygiene and Sanitation of the United States Public Health Service over the past twenty-five years have recently resulted in the establishment of similar agencies in the health departments of many states and some cities. In 1915 the Section on Preventive Medicine and Public Health of the American Medical Association conducted a symposium on industrial sanitation; in every succeeding meeting similar material has been presented.

Realization of the expansion of interest in industrial medicine led the House of Delegates of the American Medical Association to create the Council on Industrial Health. Correspondence on specific professional problems in industrial medicine has steadily increased and the space which has been assigned to this subject in *THE JOURNAL* has become greater and greater. Indeed, all the councils and bureaus of the Association are cooperating in the aid of physicians who need assistance in meeting the problems of adequate industrial medical care.

The record of achievement is gratifying to all who have contributed toward the elevation of standards and practice in industrial health. As in the case of workmen's compensation, the solution of some problems has only served to demonstrate the presence of others. The necessity for continued concentration on and devotion to the contribution which medicine can make to minimize the ill effects which occupation and working conditions may have on the health and well-being of the individual worker is apparent.

METAPLASTIC IMMUNITY

According to MacNider¹ of the University of North Carolina, there are variations in the resistance of individual tissue cells to toxic agents. As a result of this variation less resistant cells are killed by the properly graded dose of toxins, selective hypertrophy or regeneration of the relatively resistant remaining cells rendering the organ or tissue relatively immune to this toxin. His earliest demonstration of this "metaplastic" immunity was a study of acquired uranium tolerance in the kidneys. Following the subcutaneous injection of 2 mg. of uranium nitrate per kilogram of body weight, acute nephritis invariably develops in normal dogs. The kidneys of these dogs show degenerative changes, particularly in the tubular epithelium. A second injection of uranium nitrate made before full functional recovery

invariably increases the severity of this epithelial degeneration. If the second injection is delayed, however, till the animals have established complete functional regeneration, it is usually found that the dogs are relatively immune to uranium nitrate, 4 mg. per kilogram of body weight producing no nephrotoxic symptoms. A similar acquired tolerance to uranium in the kidney was subsequently demonstrated in rabbits.

Histologic studies of the kidney immune to uranium show a "metaplastic" repair, replacement of the lost tubular epithelium with cells of a syncytial type. This regeneration can be conveniently classified as a survival and regeneration of the "fittest" or "metaplasia," although the latter word is open to criticism.

Following his initial demonstration of metaplastic immunity in the kidneys, MacNider demonstrated similar syncytial regenerations in the liver. Following the subcutaneous injection of a dose of uranic nitrate sufficient to cause metaplastic regeneration, the animals acquired a tolerance to uranium accompanied by a tolerance to various other hepatotoxic agents, including chloroform. Studies of dogs in which this syncytial type of hepatic regeneration had been produced many months previously showed that the acquired hepatotoxic tolerance can persist for at least four years. Focal reversions of the liver cells to the earlier chloroform susceptible types, however, were occasionally demonstrable.

That metaplastic regeneration actually takes place in animals maintained under normal conditions is shown by MacNider's study of eighteen senile dogs. Thirteen of these dogs showed a normal liver function as far as could be determined by the phenoltetrachlorophthalein test. These animals, however, were completely resistant to a normally necrotizing dose of chloroform. Histologic study showed numerous syncytial cells in the liver.

Thus far, immunologic theorists have shown but slight interest in MacNider's concept because his work has been limited to highly specialized parenchymatous tissues. If a similar selective regeneration can be shown to be operative in the spleen, bone marrow and other parts of the reticulo-endothelial system, however, his metaplastic theory may form the basis for some future theory of specific antibody production. Recent studies of *in vitro* production of specific antibodies by splenic fragments seem to be in accord with his theory. Only after splenic tissues have recovered or regenerated from specific antigenic assault do they have the power to produce corresponding antibodies *in vitro*.² Whether or not this "preparedness" is due to selective regeneration or to metaplastic proliferation, however, has not yet been determined.

Current Comment

"YOUR HEALTH" ON THE AIR AGAIN

Beginning October 19 and for thirty-six weeks thereafter the American Medical Association and the National Broadcasting Company will again unite in offering the American people the radio feature *Your Health*. Details as to date, time and topics will be found either under Association News or in the Organization Section of *THE JOURNAL* and monthly in a radio department supplementary to the programs in *Hygeia*. This radio program, which received the First Award in its classification from the ninth annual conference of the Institute for Education by Radio,¹ thus enters its fourth year of dramatic presentation, its sixth year of continuous fall, winter and spring broadcasting and its second year in a form designed specifically for supplementary use in connection with health teaching in the schools. The program has been used for health teaching by the schools in New York, Chicago and numerous other cities in all parts of the United States. Comments relative to it have been received from the British Isles, where it has been heard through short wave broadcasting. It is based on the conception that health teaching can be enriched and its value enhanced by presentation of health situations in interesting and amusing dramatic form with appropriate musical interpolation, all presented under the experienced direction and by the able artists of the staff of the National Broadcasting Company. The ultimate usefulness of such a program depends on its local reception. All that the American Medical Association and the National Broadcasting Company can do is to put the program on the network. To be effective, it must be broadcast by as many as possible of the local stations affiliated with the network; of these only a few are owned and operated by the National Broadcasting Company and only over these has the network any control. All other stations affiliated with the network may broadcast the program *Your Health* locally or they may not. Their decision depends largely on whether or not revenue-producing local programs are available at the same time. In many instances when the program *Your Health* has not been broadcast it has been because of previous commercial commitments. Therefore local medical societies and auxiliaries should make immediate contact with the managers or program directors of the local stations on the Blue network of the National Broadcasting Company as listed on page 945 of this issue of *THE JOURNAL* and inform them as to the character of the program *Your Health* and the day and hour when it will be on the network. In most instances radio stations are eager to use good educational broadcasts if they learn about them in time to avoid conflicts with revenue-producing features, which latter obviously the station must have if it is to pay its expenses. In some instances when commercial commitments already have been made it may be possible

by conferring with the commercial sponsor to effect a change of schedule satisfactory to all concerned which will permit the local broadcasting of the program *Your Health*.

DEATHS FOLLOWING ELIXIR OF SULFANILAMIDE-MASSENGILL: VII

On November 6, 1937, *THE JOURNAL* published a special report under the auspices of the A. M. A. Chemical Laboratory dealing with the chemical composition of elixir of sulfanilamide-Massengill, pharmacologic work reporting results following the administration of elixir of sulfanilamide-Massengill, and pathologic studies on the necropsy material from both animals and man. In addition there was a map indicating where the deaths had occurred. The pharmacologic and pathologic reports by Drs. Geiling and Cannon indicated that further investigations were under way. The preliminary investigation showed that there was no essential difference in the results whether elixir of sulfanilamide-Massengill in the doses recommended or comparable doses of a "synthetic" mixture or of diethylene glycol were administered. In the more extensive work by Geiling and Cannon (reported elsewhere in this issue¹) these conclusions have been confirmed. In addition the authors have had an opportunity to study the possible mechanism of the action of the elixir and of diethylene glycol alone. They again report that the pathologic picture is essentially similar in the different species of animals when given the three preparations containing diethylene glycol that have been enumerated; that the pathologic changes were apparently those of a severe chemical nephrosis with intracellular edema of the epithelial cells of the convoluted tubules resulting in tubular obstruction by compression and by the intraluminal formation of casts. This intracellular edema in the kidneys leads to internal disorientation of cells of the convoluted tubules and offers an explanation for the tubular obstruction, anuria, uremia and death. Whether this intracellular change is due to cellular anoxia or whether it is due to hygroscopic properties of diethylene glycol are questions needing further investigation. In analyzing the composite clinical picture they bring out that there was apparently considerable variation in the responsiveness of patients to elixir of sulfanilamide-Massengill. They examined tissues of fifteen persons who died following the use of the diethylene glycol-containing elixir. Their observations coincided essentially with those reported by Drs. I. A. Nelson and H. A. Ruprecht and by Dr. Hagebusch as well as by a number of others.² Evidently the time interval between doses and the concentration in which the elixir was recommended for human use exceeded the capacity of the body to handle the drug without producing serious injury. The pharmacologic staff of the Food and Drug Administration at Washington is conducting experiments which according to unpublished reports are in general accord with the observations reported by Drs. Geiling and Cannon.

1. Geiling, E. M. K., and Cannon, P. R.: Pathologic Effects of Elixir of Sulfanilamide (Diethylene Glycol) Poisoning. A Clinical and Experimental Correlation, Final Report, this issue, p. 919.
2. Drs. Harry C. Schmeisser, T. C. Moss, C. E. Gillespie and K. M. Lynch have reported similar results.

ORGANIZATION SECTION

AMERICAN MEDICAL ASSOCIATION STUDY OF MEDICAL CARE REPORT FROM ROCK COUNTY, WISCONSIN

The study of need and supply of medical care inaugurated last February¹ by the American Medical Association through its state and county medical societies is progressing. Study forms and instructions to assist state and county medical societies in the study of medical care have been sent on request to forty-three states and the District of Columbia.

Several county medical societies have already finished their local studies of the need and supply of medical care and have sent completed summary sheets and reports of findings and recommendations to the Bureau of Medical Economics. Following are the results of the study made by the county medical society of Rock County, Wis. Other reports will be published from time to time.

ROCK COUNTY, WISCONSIN

Rock County covers an area of 716 square miles in the extreme southern portion of Wisconsin. The county forms part of the Illinois-Wisconsin state line, approximately midway between Lake Michigan and the Mississippi River, and lies in a manufacturing and dairying district. According to the 1930 census the population of Rock County was 74,206. The two main population centers are the cities of Beloit, with a population of 23,661, and Janesville, with 21,628 persons. A total of 30,041 persons were gainfully employed in 1930: 12,719 in manufacturing industries, 11,765 in trade, service and other nonmanufacturing industries, and 5,557 in agriculture.

In economic status Rock County ranks seventh of the seventy-one counties in Wisconsin, according to the Wisconsin Regional Planning Committee. This ranking is based on weights given to factors such as per capita income, percentage of population on relief, employment, occupational trends and health. However, with regard to health, as measured by birth and death rates in relation to average birth and death rates for the state, Rock County was ranked forty-eighth.

The study of medical care in Rock County was conducted under the auspices of the Rock County Medical Society by the board of trustees, Drs. G. W. Belting, president, C. R. Gilbertson vice president, O. W. Friske secretary, Wayne A. Munn, H. E. Kasten, W. T. Clark, F. Van Kirk and W. O. Thomas. By seeking the cooperation of all individuals and organizations concerned with medical care in Rock County, such as physicians, dentists, nurses, pharmacists, hospitals, health departments, welfare and relief agencies, schools, colleges and other organizations, this study committee determined the supply of and the need for medical services in Rock County, as follows:

An inventory of the medical services and facilities was made which revealed that there are 102 physicians: eighty-eight in active practice, three in administrative positions, and eleven retired or not in practice; sixty

dentists; fifty-two full time and ten part time private duty nurses and four full time and two part time public health and visiting nurses available for nursing care of the sick in their homes; five hospitals: three general hospitals with a bed capacity of 218, one tuberculosis hospital with sixty-eight beds and one mental hospital with 330 beds; thirty-five pharmacists; four clinics—two operated by the health departments and two by welfare and relief agencies—providing for general medicine and surgery, maternal and child welfare, eye, ear, nose and throat, nervous and mental, venereal disease, tuberculosis and dental patients; seven health departments; one private and two government agencies which arrange for or provide services such as care in physician's or dentist's office, medical care in the home, hospitalization, drugs, eyeglasses and surgical appliances; twenty schools below the college level providing health supervision services for pupils; one college with a student health service, and seven other organizations such as mutual benefit associations and fraternal orders which arrange for or provide medical services.

Such a matter of fact inventory served a useful purpose by indicating the nature and extent of the agencies through which medical services are made available to the residents of Rock County. For example, there is a physician in active practice for every 843 persons in Rock County, which is fewer persons per physician in practice than the average for the United States. No person in the county would have to travel farther than fifteen miles to reach a physician. During 1937 general hospital beds in private rooms were 76 per cent occupied, in semiprivate rooms 55 per cent and in wards 63 per cent, indicating that general hospital beds are fairly well distributed according to room accommodations and that the number of such beds seems more than adequate. The daily room rates charged, \$2.50-\$3 for a ward, \$3-\$4 for semiprivate and \$4.30-\$6 for private accommodations, are not excessive.

The question of availability of medical services for indigents and for low income persons was investigated fully. More than 3,000 persons received free medical service direct from physicians and dentists in the office, home or hospital. Over 500 patients received hospital care, free or at public expense, from hospitals within the county, in addition to some 200 patients sent at public expense to the Wisconsin General Hospital in Madison. More than 27,000 days of hospital care were provided at no expense to the patients. Nursing visits made without charge to patients numbered more than 4,500. Eighteen pharmacists compounded 390 prescriptions without charge and 5,954 prescriptions at cost or reduced fees.

Information obtained from all sources indicates that medical services are readily available in Rock County. The health department, with thirty requests for medical care, reported no difficulty in obtaining such care. Of 162 persons reported to the health department as in

1. J. A. M. A. 110:77B (Feb. 12), 127B (March 5) 1938.

need of medical care which they were not receiving, the causes were unemployment or inadequate income and a lack of knowledge of the procedure for obtaining medical care. Approximately one fourth of these persons did not desire medical care because of indifference or unwillingness to cooperate with any social agency.

COMMENTS ON THE NEED FOR MEDICAL CARE

Some comments on the need for medical care were as follows:

From physicians:

There is no one in Rock County who cannot secure medical, dental or hospital service. Every one can secure aid, unless they are too lazy to come and see a doctor. Our outdoor relief takes care of any one that is indigent for any reasonable illness; the only thing excepted is chronic pelvis relaxations, hernias, and things not causing acute trouble. There are some borderline deadbeats who drink up all of their money that do have trouble routing out a doctor at night, but the next day they can secure aid at the hospital for any acute illness. The family welfare, visiting nurse association, and all agencies bring these people to the doctor.

I have found no cases in which a patient was refused care because he was unable to pay. I have found many cases referred by agencies such as the Family Welfare, Crippled Children's Association, the Police Department, Municipal Hospital, where the doctor's services were expected gratis and no attempt was made by those organizations to secure compensation for the physician. I have found several cases where payment for adequate care of the patient has been refused by the relief agencies but has been carried out at his own expense by the physician.

It is my belief that in Rock County there is no need for medical services that is not supplied by the County Welfare Department, the health departments of the county and cities, and private welfare agencies as well as those supplied by the County Judge under the state law. The public welfare department not only supplies necessary medical care but such care as may seem indicated to prevent possible disability and dependency in the future such as removal of tonsils and infected teeth. Glasses are supplied to school children who need them and also to adults whose defective vision may incapacitate them for doing their regular work or who if supplied glasses could be put to work. Hernias are treated with trusses or if the individual is young and would be taken into private employment after operation, operation is authorized. In other words, medical service meets not only emergency needs but has been placed on a constructive social basis with the idea of returning disabled persons to useful employment. Strict supervision is kept over all medical services rendered to the end that unnecessary medical expense is not authorized and the cost to the community is kept within reasonable bounds. Consideration is given to all elements of society in an effort to be fair to the patient, the taxpayer, and the physician.

From dentists:

I believe the present system used in Rock County is very good, efficient, and fair to the profession and the public.

The local relief takes care of the operative cases needing extraction, but otherwise persons do not get the work they should have done, such as just ordinary extractions where no local or systemic reaction is noted; and practically no restorative work is allowed on any except minors and many are in need.

People who are not being treated have every opportunity to receive dental care so far as I know—either through the county setup or by private dentist.

From a hospital superintendent:

All of the hospitals of the county are of the opinion that the people are receiving adequate medical care through the relief setup. They, however, deplore the fact that the county is unable to pay only such a small fee as is stipulated in their contract.

It is the general feeling of the supervisors of hospitals that relief patients in general receive much better care than the borderline type of individuals.

From health officers:

In Beloit any one who wants to be vaccinated, have shots for diphtheria or a tuberculin test can get it free of charge and is urged to do so. Indigents requiring medical care can easily get whatever they require through the Relief Office. I believe the problem here is how to get hospital care and laboratory and x-ray work for self-supporting people of the low income group.

From my observation, there are many adults and children who very badly need medical care. Many of them insist they are unable to pay current medical fees. One or two have bitterly criticized these as being too high. Many families needing care do not appreciate its value and it would seem that only through much more education of the general public can this attitude be changed.

From pharmacists:

We have very good facilities for the needy to get aid under our existing county aid and city health office. If people properly apply, they will be taken care of and so far we have had no complaints, and I wish to comment on the policy that the patients have their choice of the doctor, and the doctor has freedom to prescribe what he knows best for their individual needs, not being limited or restricted in a real humane cause.

The patients on county relief do not hesitate to call a physician and probably get more medical attention than the average individual who has to pay for services. The above statement does not infer that they receive better service; it only means they receive more in proportion. The present system is much preferred to having only two or three physicians in the whole county take care of these people. We do not receive a fair remuneration for our services, so we accept what is forced upon us.

RESPONSIBILITY OF LOCAL AUTHORITIES

The development of the present arrangement for the care of indigents in Rock County illustrates the struggle that is often necessary to get local authorities to recognize their responsibilities to the indigent sick. Prior to 1932 the indigent sick in Rock County were cared for by two physicians hired by the county board on a part time basis. The operation of this arrangement is described as follows:

Each physician received \$100 a month, plus allowances for drugs and for obstetrical cases over and above a minimum which was stipulated in the contract. This system was very unwieldy and the county physician was completely "swamped" with work, patients frequently having to wait several days for an appointment to see the county doctor. Every one was dissatisfied because they were forced to accept the services of a certain physician whether they liked him or not, and obviously this man could not render effective service to the great number of people he was expected to care for.

Additional funds for the medical care of the indigent sick could not be obtained, so the Rock County Medical Society created "Cooperative Medical Clinics, Inc.," to operate two clinics for indigents with all services donated by physicians. Drugs and hospitalization could be obtained in an emergency case. By February 1933 the families on poor relief had increased to 3,143 and the burden of free medical care was becoming too heavy for physicians to carry. A committee from the medical society secured a temporary agreement with the Rock County Board of Supervisors whereby certain patients who could not be cared for by the county physician could receive care from other physicians, who would be paid 50 per cent of regular minimum fees.

Finally the members of the Rock County Medical Society concluded that it was no longer possible for

physicians to carry the ever increasing load of medical care for relief persons, and the following resolution was passed:

WHEREAS, The care of the indigent is properly and legally a government function; and

WHEREAS, Medical, dental, surgical and hospital care is specifically mentioned in the laws of the state along with food, clothing, heat and shelter as necessities which must be furnished the indigent; and

WHEREAS, The medical and dental professions have for a great many years carried an unfair proportion of relief work along this line; and

WHEREAS, The situation is such that we can no longer continue to do this work gratis; and

WHEREAS, The care of the indigent is a county responsibility and the failure of the county to assume its obligation operates to deny the larger group of citizens who are striving to maintain an independent status in life the lesser rates which physicians would receive in the event that they did not have to carry the complete load of the indigent; therefore, be it

Resolved, That the members of the Rock County Medical Society, and the Rock County Dental Society in special meeting assembled, go on record that they can no longer gratuitously care for the indigent.

A committee was then appointed to meet with the county board of supervisors, and after many stormy sessions an agreement was reached whereby indigent persons were to have free choice of physician. The physician would receive 50 per cent of his regular minimum fee. Hospitals were to provide hospital care at a minimum rate of \$17 weekly plus certain extras provided in the fee schedule, and pharmacists were allowed 20 per cent above cost for drugs and medical supplies. A description of the operation of this agreement for the care of the indigent is given as follows:

A physician is given an order to care for an indigent patient by the Rock County Relief Department. Attached to this order is a double postcard upon which the patient's physician must make an immediate report and an estimate of the number of visits or the type of medical work which the patient requires. All indigent patients have an absolute choice of physician and may get a relief order to see any one they wish. The only restriction being placed upon them is that they must keep the doctor they choose for at least one month and cannot change doctors until the following month unless for very urgent reasons. In case of surgical work or any extended illness, the consultant for the county board must see the patient before any expense is involved to determine the necessity for special care. The Committee on the Care of the Indigent [consisting of four physicians appointed by the medical society] meets on the first Tuesday of every month to audit all bills presented for the indigent.

The Relief Department makes an investigation of the financial and social history of patients in order to determine whether or not their income justifies public assistance. General hospitals do not maintain charity wards, and every one is expected to pay unless authorized as eligible for public assistance by the Relief Department; nevertheless, as has been indicated, many patients receive free services in the hospital. Nursing organizations are reported to follow no definite procedure in determining inability of patients to pay. Also, as has been indicated, physicians render services at greatly reduced fees for persons on relief and free services to thousands of their own patients in addition to the hours of service spent in clinics. Indigent tuberculous patients are given free hospitalization in a county sanatorium. A county institution for the care of the aged and the chronically insane is also maintained which furnishes medical and surgical services for inmates at county expense.

ATTITUDES TOWARD ARRANGEMENTS FOR CARE OF INDIGENT SICK

The attitude toward the present arrangements for the care of the indigent sick was expressed as follows:

It was unanimously concluded that, as far as the indigent of Rock County are concerned, this phase of the care of the sick no longer presents a problem. All indigent in this community are excellently cared for as is every one who might have any possible claim upon governmental facilities for assistance in his sickness care.

The success of the arrangement for the care of the indigent has made it possible for the medical society to secure the approval of the county board for the formation of a county sanitary unit consisting of a health officer and a sanitarian. This proposal was previously turned down by the county board.

The problem of hospitalization for indigents has a special aspect in Wisconsin because of the existence of a state law which makes it mandatory on the county judge to send a patient to the Wisconsin General Hospital in Madison if the patient selects that institution. Under this law each county is given a quota of patients who may be sent to the Wisconsin General Hospital and for whom the state will bear one half of the expense and the county the other half. Consequently, Rock County must pay \$2.10 a day for all patients within a quota of 128 who select the Wisconsin General Hospital and \$4.20 a day for those patients who exceed the quota. The Study Committee felt rather strongly that this law should be changed so that the indigent patients may be hospitalized at home. Their attitude is expressed as follows:

Briefly, our County Judge has spent \$24,000 for the hospitalization of cases in the Wisconsin General Hospital during the past year, taking care of only 232 cases, while the Rock County Medical Society in its setup with the Rock County Welfare Department has hospitalized 271 patients, paid the doctors and furnished postoperative care and drugs at home for only \$17,590. The total cost of office, home care, obstetrical, and everything for the thousands of patients cared for by our Relief Department during the last fiscal year was only \$37,000. This seemed to prove to the Board of Trustees that the pernicious practice of sending patients out of the county and increasing the tax burden would have to stop. . . .

We feel we can do a better job more cheaply in our local institutions than can be done on the ordinary routine cases which are being sent away. It will always be necessary to send certain complicated cases which are especially suitable for teaching purposes to the Wisconsin General Hospital, but it is felt that the great majority of the indigent should be taken care of with our own county facilities. . . .

The Study Committee also advises the substitution of a medical committee in each county of the state for the services now performed by the county judge, this committee to have full power to determine whether or not it is necessary to send a patient to the state institution or whether there are ample facilities in the county to care for the individual. It is felt that this arrangement would be more fair to the patient, the physician, and the taxpayers of the county.

It is also pointed out that there are two distinct agencies—the relief department on the one hand and the county court on the other—handling medical relief. This, it is said, causes dissatisfaction, as each agency operates under a different statutory definition of eligibility for relief and it often happens that a patient may be denied medical aid through the county relief office and still be entitled to assistance from the county court.

CARE OF BORDERLINE PATIENTS

The problem of caring for borderline patients was given special attention. This problem was outlined as follows:

In an industrial community such as is reported by Beloit and Janesville, about 60 per cent of the total population may be classed as borderline patients in such times as we are just now experiencing. With the various shops working only two and three days a week, the average pay check has been more than cut in half, and we have a great number of people who do not have anything left with which to pay for medical services.

There are literally thousands of people in this county who are attempting to maintain an independent status in life who are too proud to go to any doctor and ask for help when they are confident that they will have no funds available in the near future to make even moderate payments for their medical services. As a result of this situation, thousands of people are neglecting their teeth while dentists' offices remain empty, and very little reconstructive work on the teeth is being done. This summer, especially, people seem to be neglecting their children's tonsils because they can see no way in which they can pay even a minimum charge of \$25 for such work. It is obvious that hundreds of women are neglecting to care for cervical erosions and lacerations, and minor gynecological complaints, which are the precursors of cancer if long neglected. There are also hundreds of men in this county who are suffering from hernias of various types and who have no hope of having this condition corrected by surgery. It would be utterly impossible for them to take six weeks away from their work and then to be a semi-invalid for a couple of months longer in order to get a cure for their hernia. They cannot afford to be away from their occupation for this length of time, to say nothing of paying a large hospital and medical bill which would be involved.

We feel that some plan should be adopted whereby the large group of borderline patients can secure laboratory, x-ray and hospital facilities on a prepayment basis. This will greatly aid the physician because at the present time there are very few of these individuals who can avail themselves of diagnostic facilities, and consequently the doctor must do the best he can in treating these patients in his office without the aid of the various scientific devices whose value we have come to appreciate in the past few years. Once more allow us to say that perhaps this entire situation which we have outlined is no problem of the medical profession at all. When one compares the cost of medical care to that spent annually for cosmetics, whisky and automobiles, one often wonders why the family doctor should be concerned about people's problems in regard to their health. They seem to have money for everything else except for their own welfare. We do not know any reason why we should be especially concerned about something which does not seem to interest the average patient himself.

Some method of making it possible for borderline patients to have access to hospital, laboratory and x-ray facilities is pointed to as the real problem in arranging for the care of the low income or so-called borderline patients. The Study Committee looks to the committee of the state medical society which is studying arrangements for hospital insurance for assistance in meeting this problem, as it is believed that prepayment for the use of hospital and diagnostic facilities would not only make it possible for borderline patients to have greater access to such facilities but also that physicians would have a greater likelihood of collecting moderate fees.

The economic plight of the farmer, the industrial worker and the other persons in the low income group colors the whole problem of providing them with medical services. It was pointed out that the Rock County Relief Department has liberalized its views with regard to borderline patients and is now attempting to pay for medical services for certain low income families. However, the need of these individuals has to be great

and they are given a thorough investigation before a physician is authorized to care for them. A special arrangement for the care of the low income group was suggested by the Study Committee as follows:

We recommend that some system of reduced fees on a pro rata system be adopted at the next session of our house of delegates. In order that the medical profession may care for the low income groups in an ethical manner, it shall be universal and have the approval of the entire profession.

The committee also reported on the efforts of other organizations to help in the care of the sick in Rock County. The first of these is the Welfare Department, which receives money from the community chest to make loans to borderline patients for medical emergencies. The local clubs of fraternal orders also undertake to give assistance to certain groups of borderline persons. For example, one club arranges each summer to have tonsils removed from children whose parents are unable to care for them. Another club arranges to pay for eye examinations and glasses for certain persons in the county. A philanthropic organization arranges to care for crippled children with funds raised through the sale of crippled children's stamps. There are also several mutual benefit associations which assist employees and sometimes their dependents to receive medical care.

Most of these organizations have the cooperation of the medical society in their endeavor to make it possible for low income persons to receive more medical care. However, some of the arrangements are organized or operated in a manner which interferes with good medical practice and consequently causes dissatisfaction. For example, some fraternal orders to encourage membership have offered members medical service for minor illnesses by contracting with a certain doctor who is willing to provide services for the assessments of 25 cents to 50 cents monthly from each member. Such lodge practice has almost invariably been condemned by medical societies because it provides members with a meager, unsatisfactory service. The organization arranging for the care of crippled children is also criticized because of the tactics it uses to induce physicians to care for crippled children—while claiming credit for all the results achieved. The restrictions of the payment for care of crippled children and the aforementioned regulation whereby patients are sent to the Wisconsin General Hospital are also instanced as undesirable for proper and economical care of crippled children.

In reviewing the general thoughts which have been evolved as a result of the survey, the Study Committee concluded that "the medical profession must make arrangements to take the lead in all things medical" and that:

In general, doctors should be ashamed of themselves to have to admit that certain lay groups can point out the errors of our ways. The medical society should encourage constructive thinking along these lines and urge its members to get busy and keep the control of things medical with the doctor. We hope that the articles which are appearing in the lay press of today in regard to medical practice will soon make doctors conscious of the fact that they must begin to solve many of these public health problems for themselves and not wait until the government forces us to change our entire methods of practice. In other words, we should not be afraid to change our views in regard to the care of the sick but must keep our minds open to suggestion so that the medical profession will retain the position of honor which it has always enjoyed.

GRADUATE MEDICAL EDUCATION: CALIFORNIA

A PROGRESS REPORT OF THE FIELD STUDY ON GRADUATE MEDICAL EDUCATION IN THE UNITED STATES
BEING CONDUCTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

In 1935 the house of delegates of the California Medical Association decided to sponsor a series of statewide graduate courses for physicians in cooperation with the state's four medical schools. The University of California Medical School had been conducting extramural graduate instruction in central and northern California in 1934 and 1935, teams of faculty members participating in extension courses on alternate Fridays and Saturdays during each month of the school year. The data developed from this series were made available to a state association committee appointed to elaborate a program of statewide meetings and clinical conferences. The committee on postgraduate activities consisted of three members, with Dr. Clarence G. Toland chairman and the secretary of the state association as an ex officio member. In February 1937 members of the committee met with the deans of the medical schools, the secretary of the California Tuberculosis and Heart Association and Dr. Charles A. Dukes, chairman of the state association's committee on public relations.

A cooperative and uniform program was adopted, since it was realized by all that postgraduate activities were the most important means of raising the standards of the medical profession. The following proposals were made and put into effect: Medical schools and the state medical association were to cooperate in postgraduate conferences to avoid conflicting programs. Courses were to be arranged through the office of the executive secretary of the state association. At each graduate session an attempt would be made to cover one subject completely with a physician, surgeon, pathologist and roentgenologist participating. Conferences were to include clinical demonstrations. Local physicians with difficult cases were urged to present patients. Expenses incidental to the program were to be borne by the state association and county medical societies. Clinicians who conducted courses were to be reimbursed for travel and hotel expenses. The California Tuberculosis and Heart Association offered to provide half the expense of conferences held in lieu of its meetings. Instructors were to be selected from the medical school faculties and speakers were suggested by the tuberculosis and heart association, by the cancer committee of the state medical association and by other members of the state association. Other medical and health agencies were urged to join in this graduate effort. A five year study program putting these proposals into effect was published in November 1937.¹ Three hundred physicians and other educators offered their services under this plan.

During 1937 conferences were held in seven centers in central and southern California. The graduate committee in each local county society chose subjects from the list supplied by the state association. Of the 103 subjects offered, instruction was sought most frequently in obstetrics, gastro-enterology, pediatrics, gynecology, endocrinology, pharmacology and the clinical use of drugs, traumatic surgery, general surgery, fractures and orthopedics, cardiovascular disease, tumors and allergy. Other courses included symposiums on ear, nose and throat diseases, clinical pathologic conferences, laboratory examinations, dermatology, pneumonia, thyroid and venereal diseases. Nine hundred and fifty physicians registered for graduate training during the first year. The state association expended \$441 during 1937 for postgraduate instruction. Each county society selecting a program shared in its support. The estimated cost of postgraduate conferences for the current year is \$4,000. The chairman of the present committee on postgraduate work of the California Medical Association is Dr. John C. Ruddock.

One county society, San Joaquin, established in 1935 a permanent annual series of graduate meetings. It was proposed that each year an out of state speaker be invited to participate. At each of the seven evening programs one or more instructors would cover various phases of the subject presented. In 1935 eleven physicians instructed forty-eight members in obstetrics, thyroid, rectal, gastro-enteric and venereal disease, endocri-

nology and fractures. Each session lasted from two to three hours. A special fee of \$5 was charged for the series. This was sufficient to finance travel expenses of guest lecturers, to obtain projection equipment and to supply certificates of attendance to members of the society who were present at least 80 per cent of the time. A record of attendance showed that thirty-eight physicians attended six of the seven meetings.

In 1936 Dr. C. A. Broadbuss, first chairman of the San Joaquin county society's committee, obtained, with the aid of the San Francisco Academy of Medicine, an out of state university professor who conducted a clinic on blood diseases. Eleven other lecturers considered such subjects as pediatrics, fractures, abdominal surgery, blood, eye, mouth and throat disease, and chest diseases including roentgenology.

In 1937 the county society's graduate committee of five members organized a series of lectures on syphilis, gonorrhea, pharmacology, obstetrics and gynecology, and traumatic surgery. There is greater interest in graduate work each year, and in 1937 to encourage attendance a \$25 prize was offered to the member who wrote the best review of the course.

The annual meetings of the state association are devoted in part to graduate instruction. At the 1938 session three case histories were discussed in clinical pathologic conferences by out of state guest speakers, physicians, surgeons and pathologists. This year an out of state speaker gave a series of illustrated lectures on syphilis at the annual meeting and at twelve county society meetings throughout the state. His expenses were paid in part by the California Department of Public Health. At the annual sessions symposiums, conferences and illustrated lectures characterized the scientific meetings. The attendance in 1938 was 1,970. Of the 11,278 registered physicians in California, 5,906 are members of the state association.

From April 13 to 16, 1938, the University of California Medical School gave a short course of lectures and clinics on diseases of the digestive tract. Twenty-two members of the staff participated. Clinical presentations, outlines of treatment, and demonstrations of diagnostic and therapeutic procedures were designed to meet the needs of practicing physicians. Sessions lasted from 8 a. m. to 9 p. m. on two days and from 8 a. m. to 5 p. m. and 8 a. m. to 12 m. the two remaining days. At the conclusion of each lecture period questions were allowed. There was a two hour round table discussion. Subjects included amebiasis, intestinal worms, diabetes, constipation, intestinal obstruction, tumors and disorders of the stomach and colon, diseases of the rectum and gallbladder, appendicitis, digestive diseases of children, gastro-enteric neuroses and a discussion on vitamins. A tuition fee of \$20 included the cost of meals, a mimeographed list of diets referred to in the course and a syllabus. Announcements were sent to alumni practicing in western states and notices appeared in state and national medical journals. Thirty-eight California and five Oregon physicians enrolled.

In August and September 1937 the state university medical school in collaboration with the California Department of Public Health gave a five weeks intramural course on venereal diseases with night lectures twice weekly, members of the faculty participating. Two sessions were devoted to bacteriology and pathology, three to pharmacology, four to practical clinical management and one to public health aspects of the problem. Demonstrations of clinic cases supplemented the lectures. All practicing physicians were invited. No registration fees were charged.

The University of California Hospital and Clinic offers diagnostic facilities to rural physicians of the state who desire consultative services. Patients unable to afford adequate medical examinations may be referred to the university's medical center for study. After a comprehensive investigation, patients are returned to their own physicians with the staff's report and recommendations. This is considered a practical postgraduate conference. Over the past ten years more than 2,200 practicing

¹ Supplement to California and Western Medicine 47:1-13 (Nov.) 1937.

physicians have availed themselves of this service. From 300 to 360 patients from rural areas are seen in the clinic each month.

The California legislature in 1931 established a state medical library under the control of the University of California to supply registered physicians, surgeons and medical institutions with medical library services, and \$42,176 was allocated from the contingent fund of the Board of Medical Examiners for its support. An office was established at the state university medical library in San Francisco, and a southern section was established in Los Angeles. Reference service was offered and the resources of this university's library were made available to physicians of the state. Books, journals, reports, documentary reports or other material were available for loan for seven day periods, subject to transportation charges.

During the first year a librarian visited practicing physicians outside the metropolitan areas of the state, personally interviewing approximately 12 per cent of the profession. A circulating periodical service was established enabling physicians to receive regularly one or more journals in fields of special interest. Books not on reserve were mailed on request. Analysis of items lent to June 1933 showed that 607 borrowers in 140 communities had used 1,049 books and journals. At present approximately 875 physicians are using the facilities of the two sections of the state medical library. Periodicals most frequently desired are those relating to surgery, pediatrics and otorhinolaryngology. Other special journals in laboratory diagnosis and biochemistry also are in demand. British and German specialty journals are extensively circulated. The state medical library cooperates with the Lane Medical Library in San Francisco and the Barlow Medical Library in Los Angeles.

Four years ago, Stanford University School of Medicine offered a series of postgraduate review courses in cooperation with the San Francisco Department of Public Health. The six courses offered during one week in September 1935 were in cardiology, diseases of the chest, obstetrics and gynecology, syphilis, proctology and surgical anatomy for general physicians and a course for specialists in ophthalmology. Instruction was given each morning from 8:30 a.m. to 12 m. in three general courses and from 1:30 to 5 p.m. in three others. A physician could register for one morning and one afternoon course. Three evening lectures were held during the week in nephritis, hypertension, endocrinology and gastro-enteric diseases. More than twenty-eight staff physicians participated in the general instruction and five in the specialty series. Training was available at clinics, demonstrations, examinations of patients in the outpatient department and wards, in pathologic, roentgenologic, medical and surgical symposiums and in a dissecting room. Announcements were sent to all practicing physicians in California and to the secretaries of county medical societies in Oregon, Washington, Nevada, Utah and Arizona and the component societies of Hawaii. Notices appeared in state and national medical and scientific journals. A registration fee of \$20 was charged in 1935, when 149 physicians enrolled. Courses in obstetrics, proctology, cardiology and anatomy were popular.

In 1936 there were four morning courses in obstetrics and gynecology, gastro-enterology, pediatrics and cardiology (enrollment limited to fifteen) and four afternoon courses in hypertension and nephritis, neurology and psychiatry, fractures and traumatic surgery and proctology (limited to fifteen physicians). A morning and afternoon course was given in otorhinolaryngology for specialists. General evening meetings on roentgen therapy, backache, blood diseases and syphilis were included. More than fifty members of the faculty instructed 183 physicians who registered. Greatest interest was shown in fractures, traumatic surgery, obstetrics and gynecology, gastro-enterology and hypertension and nephritis.

Eight courses were offered to practicing physicians in 1937. These were on x-ray diagnosis and therapy (for physicians with experience in this field), emergency surgery and fractures, diseases of the genito-urinary tract, cardiology and electrocardiography, diagnosis and treatment of malignant tumors, surgical anatomy and operative technics (additional fee of \$10, enrolment limited to twenty-four) and the diagnosis, treatment and control of syphilis. Ward rounds in medicine (limited to fifteen physicians) and clinics in the medical specialties, including clinical pathologic conferences, were provided. A

general meeting on the evaluation of new drugs and another on problems in industrial health were held on two evenings. One hundred and thirty-nine physicians registered; two thirds of them had not previously enrolled. Emergency surgery, medical specialties, malignant tumors, cardiology and surgical anatomy were the courses best attended. A comprehensive syllabus with references, charts, diagrams and tables on malignant tumors was supplied to physicians enrolling for instruction in this subject. Registration fees in 1936 and 1937 were \$25. The facilities of the medical school and of the San Francisco Hospital were utilized for this graduate training.

Stanford University School of Medicine has, in addition to cooperating in the state association's graduate program, supplied county societies in northern and central California with teams of faculty members on request. Seven sections of the state have been furnished with programs recently.

The medical education committee of the Alumni Association, College of Medical Evangelists, has sponsored a postgraduate assembly in the fall of each year since 1934 and a clinical congress each spring since 1932. The chairman of this committee, Dr. G. M. Taylor, is assisted by four other members. At the postgraduate assembly eighteen lectures are given at half hour intervals during one day from 9 a.m. to 9 p.m., time being allowed for luncheon and dinner. All fields of medicine are considered. Speakers include members of the faculties of the state's three other medical schools and one or more lecturers of international reputation. All practicing physicians are invited and the attendance has varied from 400 to 500 each year.

The clinical congress held in the spring is conducted by members of the faculty of the College of Medical Evangelists. Morning symposiums, afternoon clinics, demonstrations and exhibits and early evening lectures followed by a clinical pathologic conference characterize the day's program. This year symposiums were devoted to the preoperative and postoperative care involved in surgical specialties, including anesthesia and medical complications. Ten physicians and surgeons participated in symposiums. In the seventeen demonstrations and exhibits thirty members of the faculty considered such subjects as fever therapy, orthopedic surgery, proctology and medical and visual education, utilizing patients, models and motion pictures. A registration fee of \$1.50 was charged, no fees being required of medical students, interns or residents. The facilities of the college are used for these graduate assemblies.

The Department of Urology, College of Medical Evangelists, offers a course in diagnostic urology, including diagnostic technics, one morning each week. Two physicians can be accommodated. A fee is charged. A volunteer residency is available in urology. This is of from three to twelve months' duration. A short refresher course lasting from one to two months consists of observations of diagnostic and cystoscopic procedures.

The University of Southern California School of Medicine offers graduate courses in surgical anatomy, material and instruction being available for special dissection in otolaryngologic and neurologic anatomy. Graduate courses are scheduled in other preclinical departments and are open to qualified physicians.

The California Department of Public Health has conducted clinics for crippled children since 1927. Fifty or more patients may be seen in one of these clinics by visiting orthopedic surgeons who consult with the local physicians.

The California Tuberculosis Association has visited approximately three fourths of the counties of the state in connection with case finding studies or educational programs. When a clinic is held the interest and cooperation of the local county society is obtained. Local physicians may participate in the examinations and obtain professional training, including instruction in tuberculosis testing and x-ray interpretation. The annual meeting of the tuberculosis association is held over three days prior to the annual session of the state medical association. In the clinical section last year such subjects as pneumothoracic surgery, symposiums on syphilis and x-rays, and diagnostic problems in tuberculosis were included. The attendance varies usually from 300 to 500.

The Heart Committee of the San Francisco County Medical Society and the San Francisco Tuberculosis Association was organized in 1930. The postgraduate course offered that year

without fee to physicians practicing in northern California was attended by 227 physicians from sixty-five cities and towns. Each succeeding year a two day postgraduate course has been offered with constant increase in interest and attendance.

In 1935 the California Heart Association was organized and expanded the postgraduate activities initiated by the San Francisco committee. The eighth annual postgraduate symposium was held in November 1937. The facilities of ten local hospitals were used with lectures, demonstrations, afternoon study groups—each limited to from five to ten physicians—and case presentations. Members of the faculties of the two medical schools in San Francisco and other physicians conducted the symposium. A fee of \$2 was charged for two days' training. Three

hundred practicing physicians registered and a mimeographed syllabus was supplied to each.

The Los Angeles Heart Association offers an annual course for physicians practicing in the southern part of the state. A round table discussion of the physiologic, clinical and pathologic problems in heart disease featured the 1937 fifth annual symposium. In addition to lectures, exhibits of pathologic specimens and electrocardiograms were on display at the Los Angeles County Medical Association Building. A \$2 fee was charged.

In 1938 the California Heart Association held a four day symposium concurrently with the annual meeting of the California Medical Association. This was arranged by the state medical association's committee on postgraduate work.

OFFICIAL NOTES

DATE OF ST. LOUIS SESSION

The next annual session of the American Medical Association will be held in St. Louis, May 15 to 19, 1939.

THE RADIO PROGRAM "YOUR HEALTH"

Resumption of Broadcasts October 19 for
Thirty-Six Weeks

The American Medical Association and the National Broadcasting Company will resume the radio program Your Health beginning Wednesday October 19 and running consecutively for thirty-six weeks thereafter. The program will be broadcast over the Blue network of the National Broadcasting Company each Wednesday at 2 p. m. Eastern Standard time (1 p. m. Central Standard time, 12 noon mountain time, 11 a. m. Pacific time).

This will be the fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health. The radio scripts will be written by Leslie Edgley, an independent radio script writer affiliated with the Artists' Bureau of the National Broadcasting Company and author of the successful radio dramatic feature "There Was A Woman." Material for the scripts will be furnished by the Bureau of Health Education of the American Medical Association.

The medical societies can do much to influence the local radio stations to carry this program, by showing an interest in it and by informing the local manager, as well as the local school authorities.

The following is a list of the stations connected with the Blue network of the National Broadcasting Company, but no assur-

ance can be given as to how many of these stations will broadcast the program Your Health:

Basic Blue Network

WJZ	New York	WEBR	Buffalo	KSO	Des Moines

WSOC	Charlotte	WAVE	Louisville	KWG	Stockton
		WSM	Nashville	KMJ	Fresno
		WMLJ	Milwaukee	KERN	Bakersfield
		WTBA	Madison		

The programs to be broadcast in the first group, together with their dates and their topics, are as follows:

October 19, What is Health?
October 26, Growing Strong.
November 2, Seeing and Hearing Well.
November 9, Healthier Boys and Girls.

These programs will be broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore, local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

MEDICAL ECONOMIC ABSTRACTS

STATE MEDICINE PROPOSED IN NEW ZEALAND

In spite of its international fame for morbidity and mortality rates lower than those of any country with sickness insurance or state medicine, the Labor Party, now in power in New Zealand, has presented a program of social pensions which includes "a universal general practitioner service free to all members of the community who require medical attention."¹ The Prime Minister states that the scheme embraces free hospital or sanatorium treatment for all, free medicines and free maternity care, including maintenance in a maternity house and a grant to assist mothers in special circumstances to provide outfits for their babies. No provision is made for specialist services outside of hospitals, although some statements

from the government indicate an intention to add these later. Critics charge that the additional expenses required by the additional and increased pensions plus the medical service will almost double a present very high tax rate.

Some form of sickness insurance has been under discussion for several years. Representatives of the New Zealand Branch of the British Medical Association have held numerous conferences with members of the ministry to discuss proposed medical programs and, while agreeing to do their best with whatever scheme might be introduced, have insisted that since the results achieved in the protection of health under the system of private practice in New Zealand were already so greatly superior to those obtained in countries with sickness insurance and state medicine, it would be better to develop and improve that system than to abandon it in favor of any universal governmental scheme of medical practice.

Just how closely the medical professions agree on the effect of contract and governmental schemes of medical care on the

1. (a) New Zealand Herald, April 4, 1938; (b) National Health Insurance Section, Supp., New Zealand M. J. 37:9 (April) 1938.

quality of the medical service is illustrated by the following extracts from a statement of the chairman of the National Health Insurance Committee of the New Zealand Branch of the British Medical Association submitted to the Minister of Health of New Zealand:²

The relationship which is established immediately a patient summons a doctor has been, and always will be, a strictly personal relation of a very special sort—*independent of fee or the standing of the patient.* Medical service has a personal and confidential character which is as many sided as human nature itself and touches at every point in people's lives. The confidence of the patient implies corresponding responsibility on the part of the doctor, and no limits can be set to what may be required of it.

Consequently medical service does not lend itself readily to terms of contract like the supply of a definite number of standard articles, or the giving of so many hours of specified work. Contract necessitates limitation of responsibility. There would be the tendency for the doctor's services to be limited by the terms of the contract rather than by the exigencies of the case. If only part of the doctor's services are on a contract basis, the stimulus of private practice tends to maintain the standard of his contract work.

For this reason contract practice has been and should remain, restricted to conditions in which no other more satisfactory arrangement can be made. . . .

Nowhere does Health Insurance set standards, nor are its standards maintained by its own regulations and definitions. It is unheard of for any one to seek to advance his professional standard and method by study or emulation of Health Insurance work. The standard is set by the best of voluntary, uncontrolled, private or honorary practice, which it is therefore important to preserve in as large a body as possible. . . .

Professional organizations such as the Faculties of Medicine of Universities, the Colleges of Surgeons and Physicians and Medical Associations, such as our own, are the chief agencies through which medical knowledge, system and ideals have been promoted, developed and promulgated. . . . This policy has been responsible for the preeminence of British medicine as similar policy was for the initiative displayed by German medicine two generations ago, and it is for the prestige of American Medicine today. . . .

The adoption of a universal scheme would lead to those very distinctions which it is the object of this association no less than of the government to avoid. A certain number of doctors would prefer to remain outside the scheme, and a certain number of people would prefer to make their own arrangements as they have done heretofore, although being entitled to medical benefits under the scheme. While there might be few who would do this habitually, many would on occasions. Thus there would grow up two types of practice from which we so far, fortunately, have been free—panel practice and private practice. Even if both were in fact equally efficient, the former would come to be regarded as the "poor man's" practice. . . .

Unfortunately the average patient is not conscious of the necessity for treatment to be based on accurate diagnosis, as witness the millions spent on patent medicines. All he asks for is treatment, and under a panel scheme without ancillary services treatment may well become empirical. . . .

What we have all along wished to emphasize is that the promotion of health is a greater object than the treatment of sickness, though we do not underestimate the latter; and that National Health Insurance, being really a system of indemnification for sickness, does not materially advance the greater object.

The medical association suggests, as an alternative to sickness insurance or state medicine, continuation and expansion of the program of health care that has already produced such famous results in New Zealand. It proposes a number of improvements in environmental conditions, including housing and better working conditions. It points out that "there are admittedly problems of nutrition requiring investigation" and suggests that if these conditions can be improved it "will do more for the people than all the dietary systems in vogue or the entire National Health Insurance formulary of medicaments." The association also urges an extension of preventive and antepartum care and emphasizes, especially, the possibilities open to the extension of research.

In regard to matters of administration the view we take is that National Health Insurance is a system invented over fifty years ago to meet difficulties in other countries which, to a large extent, have been overcome in New Zealand by following lines and methods of our own. The health insurance system involves a complicated administration of its own; and, if we superimpose on our own health administration this borrowed system, a cumbrous structure will result. We consider that it would be wiser before introducing National Health Insurance to review and amend the existing administrative machinery which has developed in an irregular manner during the rapid changes of a century's growth and settlement.

The association urges the extension of health department activity and a reorganization of hospital administration so as to obtain a better distribution both of hospitals and of the service which they supply.

BRITISH NURSING PROBLEMS

Some of the features in "Evidence submitted by the British Medical Association to the Interdepartmental Committee on Nursing Services"¹ suggest interesting comparisons with similar problems in the United States.

"There is, undoubtedly," says the statement, "an insufficiency of candidates of any type for the nursing profession, and the shortage will become still more acute in the near future on account of the extension of hospital accommodation, of the increasing complexity of medical and surgical procedures, and of the reduction of the nurse's hours of work." This shortage is charged to the interruption between graduation from what would be called high school in this country and the opportunity to enter nursing training, and on the strenuousness of the training and the work that accompanies it, as well as the discipline to which the prospective nurse is subjected. Even after graduation the salary and conditions of work suffer by comparison with other occupations.

It is rather surprising to note that it is proposed to meet these conditions by a lowering of professional standards. Military terms seem to have invaded all vocabularies, so that the question of securing additional candidates is treated under the head of "Recruitment." It is urged that discipline be relaxed and opportunities for leisure during the training be expanded.

The discussion of "Terms and Conditions of Service" arouse memories of proposals under the Wages and Hours Bill, although it is recommended that "There should be a maximum working period of ninety-six hours a fortnight," and "one free day in each week." The discussion continues with the statement that "It is desirable that there should be provided within each hospital machinery for the discussion between the hospital authority and the nursing staff of the various problems of mutual interest, including the grievances of nurses."

"Assistant nurses" with lower professional standards are proposed to undertake certain types of nursing. The examinations now given are criticized as too technical, and a "Group System for Training" is proposed by which an association of hospitals in an "appropriate area" would be "linked together to form a training unit." It is held that such a system "would probably be advantageous not only to the probationer but to the smaller and special hospitals, which would enjoy the services of a steady stream of partially trained nurses." This proposal sounds much as if the medical profession were to say to the public "We know you should have good medical care at all times, but for the little things that come up we are going to send out a sort of half-trained office girl."

UNITED STATES NOT SO BAD

That the United States is still out ahead of Great Britain in health care seems to be the opinion of Dr. J. O. Dean in a review of the Report on the British Health Services by PEP in the *American Journal of Public Health* (28:786 [June] 1938). After an analysis of the material in that comprehensive report, Dr. Dean says:

"PEP will dispel any doubt in the minds of those who feel that conditions of general well-being in the United States are unfavorable in comparison with those of Great Britain. Apparently the British attitude is to 'hit upon' rather than to develop measures fostering health. The reviewer cannot escape the feeling that despite Great Britain's more comprehensive statutory provisions for the relief or prevention of ill health, she lags far behind the United States, largely because there has been lacking a dynamic attitude permitting necessary changes to be effected in the social machinery for the better adjustment of forces producing health."

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Society News.—The Marion County Medical Society will be host to the Northwestern Division of the state medical association at a meeting in Winfield, September 15. The speakers will include Drs. Arthur Neal Owens, New Orleans, "Repair of Facial Defects"; William E. Prescott Jr., Birmingham, "Clinical Use of Ovarian and Pituitary Hormone"; Julius E. Linn, Birmingham, "Anorectal Pain and Its Clinical Significance"; Clayborne R. Whitman, Tusculumbia, "Why Some Bad Results in Obstetrical Practice?" and Ellis Dice Lineberry, Birmingham, "The Anemias, Their Diagnosis and Treatment."

Illegal Practitioner Serves Jail Sentence.—A self-styled "herb doctor," Mrs. A. L. Hinkley, was sentenced July 29 to pay a fine of \$500 and costs or to serve 140 days in jail with an additional three months in jail for practicing medicine without a license, newspapers reported. The woman was arrested following several complaints from Negro residents of Mobile that she had defrauded them of money and personal belongings under the pretense that she would cure their afflictions and ills. Two blind witnesses related her promises to restore their eyesight. The defendant denied the allegations but admitted selling the complainants herbs and roots from which they were to make a "tea" for their "stomach trouble." Unable to pay the fine, the defendant went to jail, it was stated.

CALIFORNIA

Plague Infection.—According to *Public Health Reports*, plague infection was recently proved in a pool of fifteen fleas from thirteen chipmunks shot at the Osito Girls' Camp, three miles southwest of Pine Knot, San Bernardino County.

Graduate Courses.—A series of graduate courses will be given at San Francisco Hospital September 12-16 under the auspices of the hospital, Stanford University School of Medicine and the San Francisco Department of Public Health. According to the program, subjects covered in the morning and afternoon will include traumatic injuries, acute abdominal emergencies and fractures, gynecology, diseases of the chest, practical management of hypertension and nephritis in the doctor's office, pediatrics, proctology, and surgical anatomy and operative technique. Courses for specialists in the mornings will be given in anesthesiology and otorhinolaryngology. Speakers at the general meetings in the evenings will be: Drs. David A. Wood, "Surgical Pathology"; Ludwig A. Emge, "Relation of Sex Hormones to Cancer"; Emile F. Holman and Dwight L. Wilbur, "Disease of the Thyroid Gland," and Harry E. Alderson and Merlin T. R. Maynard, "Diagnosis and Modern Treatment of Common Dermatoses."

COLORADO

Denver Creates Medical Service Bureau—Accepts Hospital Plan.—At a meeting of the Medical Society of the City and County of Denver August 16, a resolution was unanimously adopted creating a central service bureau to meet the demand for prepayment care. Dr. Paul J. Connor, Denver, was appointed chairman of a committee to work out the details of the project. At the same time the society approved the plans of the recently incorporated Colorado Hospital Service Association and accepted, without a dissenting vote, the report of its special committee which had negotiated with the service association. The decision to develop a plan for medical care of low income groups followed a survey by the society to determine whether there was a need or demand for any new form of medical practice for low income families among employed groups in the Denver metropolitan area. In the spring of 1938 questionnaires were sent to all employers in the area who employed ten persons or more. Statistical information was obtained regarding the number of employed persons in various groups whose incomes were under \$1,200 a year, from \$1,200 to \$1,500, from \$1,500 to \$2,000 and so on. Employers were also asked to indicate interest or lack of interest in such plans. Of the 35 per cent who returned full replies, the majority expressed interest in and asked for information concerning a prepayment plan and favored adherence to the basic principles of the Ameri-

can Medical Association. While actual details have not yet been worked out, the plan will be under control of the county society, will guarantee free choice of physician and will abide by the ten principles of the American Medical Association. It will not include hospital service. Cooperative and independent studies by the medical society and the Denver Hospital Council preceded the incorporation of the hospital service association. Mr. William McNary, formerly business manager of the Colorado General Hospital, Denver, was appointed executive director of the association, effective September 1.

CONNECTICUT

Personal.—Lorande Loss Woodruff, Ph.D., professor of protozoology, Yale University School of Medicine, New Haven, has been appointed chairman of the department of zoology and director of the Osborn Zoological Laboratory.

Vacancies for Physicians.—The newly created personnel department of the state of Connecticut announces examinations for positions as assistant sanatorium physician at Undercliff Sanatorium; assistant hospital physician at state mental hospitals; chief physician of crippled children division, bureau of child hygiene, and public health physician, bureau of venereal diseases. Residence in Connecticut is not a requisite. Applications will not be considered unless they are on file in the personnel department, State Capitol, Hartford, September 10 or bear a postmark not later than that date. A separate application should be filed for each position. Application forms may be obtained from the personnel division or at any office of the Connecticut State Employment Service. Candidates must be eligible for a license to practice medicine and surgery in Connecticut and must have had at least one year of general hospital internship in a hospital approved by the American Medical Association. Preference will be given to candidates who have had training or other experience in the care of tuberculous patients and to those with special training in other branches of medicine or surgery.

DISTRICT OF COLUMBIA

Alumni Extension Course.—The third annual alumni extension course of the Georgetown University School of Medicine will be held September 12-16. Out of town speakers will include Drs. Frank H. Lahey, Boston; Dean Lewis, Nicholson J. Eastman and Edward H. Richardson, Baltimore; Jerome Sefinger, New York; John Mark Higgins, Sayre, Pa., and Francis C. McCormack, Englewood, N. J. The program has been designed to interest the general practitioner, while a variety of special clinics and conferences have been arranged for specialists. The "silver jubilee class of 1913" is sponsoring the course this year.

GEORGIA

District Meetings.—The Eighth District Medical Society was recently addressed in Waycross, among others, by Drs. Raymond L. Johnson, Waycross, on "Malignancies of Sigmoid and Rectum"; Arthur G. Fort and Lester A. Brown, Atlanta, "Radical Mastoid Operation with Skin Graft" (motion picture); Henry W. Clements, Adel, prevention and treatment of eclampsia, and Henry J. Goodwin Jr., Douglas, ovarian hyperfunction. —At a recent meeting of the Sixth District Medical Society in Sandersville the speakers included Drs. Paul S. Kemp, Macon, on "Care of the Senile Diabetic"; Charles J. Woods, Macon, "Treatment of Skin Cancer"; Frederick B. Rawlings, Sandersville, "Some Surgical Aspects of Gallbladder Disease"; Robert B. Greenblatt and Everett S. Sanderson, Augusta, "Newer Venereal Diseases"; Robert C. Goolsby Jr., Macon, "Asphyxia Neonatorum"; David Henry Poer, Atlanta, "Differentiation and Treatment of Goiter," and John A. Bell Jr., Dublin, "Pneumococcus Meningitis." —The First District Medical Society was addressed in Savannah July 20, among others, by Drs. George H. Lang, Savannah, "Endoscopic Removal of Foreign Bodies from the Air and Food Passages"; H. F. Sharpley Jr., Savannah, "Practical Application of the Endocrines in the Correction of Abnormal Menstruation"; Shelton Elliott Wilson, Savannah, "Use of Sulfanilamide in Urology," and Robert Drane, Savannah, "Intestinal Obstruction."

ILLINOIS

Personal.—Dr. Loren L. Collins, Chicago, has been appointed full time medical director of the La Salle County Tuberculosis Sanatorium, Ottawa, effective September 1; Dr. Albert J. Roberts has held the position since it was created in 1919 on a part time basis.—Dr. Joseph H. Kinnaman, Charleston, W. Va., has been appointed assistant health commissioner of Peoria with supervision of school health activities, effective

August 15. Dr. Kinnaman formerly served as health officer of Topeka, Kan., as assistant health commissioner of Cincinnati, as instructor, department of pharmacology and materia medica, State University of Iowa College of Medicine, Iowa City, 1927-1930, and as deputy commissioner to the Iowa State Department of Health in charge of child health and health education activities.

Chicago

The National Health Program and American Medicine.—The North Side Branch of the Chicago Medical Society will devote its meeting September 15 to a consideration of "The National Health Program and American Medicine." The speakers will include:

Dr. Olin West, Secretary and General Manager, American Medical Association, The Conference.

Dr. Roger I. Lee, Boston, Trustee of the Association, Teaching and Practicing Medicine.

Dr. William F. Braasch, Rochester, Minn., Chairman, Advisory Committee on Supply of Medical Care of the Association, Progress of the A. M. A. Survey.

Dr. Irvin Abell, Louisville, Ky., President of the Association, American Medicine.

Dr. Morris Fishbein, Editor of THE JOURNAL, will open the discussion.

A dinner will precede the meeting, which will be held at the Drake Hotel. The meeting is open, but dinner reservations should be arranged through Miss Wolf, Randolph 0244.

Business Joins Campaign Against Syphilis.—A drive against syphilis will be launched in the city, September 5, by business groups, who will participate in a campaign started last year by the Chicago Department of Health under the auspices of the U. S. Public Health Service. Included in the cooperating agencies are the State Street Council, representing major loop merchants; the Chicago Association of Commerce, representing leading industries; the Cook County Retail Council, an organization of community merchants, and the Illinois Federation of Retail Associations, representing twenty-one city and state merchant associations. Their first step will be to provide educational and lecture material on syphilis for all employees, according to the *Chicago Tribune*. It was stated that thirty-three concerns, including steel companies, drug stores, laundries, restaurants and bakers, have provided syphilis testing programs for their employees since last April. Since last November, when the field tests began, 79,533 have volunteered, including 7,421 high school and college students and 6,742 grade school pupils.

INDIANA

Personal.—Dr. George W. Kohlstaedt was elected president of the Indianapolis board of health August 4, succeeding Dr. Maurice Joseph Barry, who has served since 1932. Frank G. Laird was elected vice president, succeeding Dr. Leonard A. Ensminger. Dr. Herman G. Morgan began his twenty-sixth year as secretary of the board August 12.

Changes in Health Department.—Dr. Lewis C. Robbins has been appointed acting chief of the bureau of local health administration of the state department of health during the absence of Dr. John W. Ferree, chief of the bureau. Dr. Ferree was to begin a year's graduate work at Johns Hopkins University September 1. Dr. Albert W. Ratcliffe has been appointed assistant to Dr. Clyde G. Culbertson, chief of the bureau of bacteriology and pathology. He graduated at the Indiana University School of Medicine, Indianapolis, in 1936.

IOWA

Spotted Fever.—A case of Rocky Mountain spotted fever was reported to the state department of health, July 13, by Dr. Ross E. Gunn, Boone, in Boone County. June 23 the state hygienic laboratory reported a positive Weil-Felix agglutination reaction on a serum specimen sent to the laboratory by Dr. Robert E. Dwyer, Preston, in Jackson County.

KANSAS

Committee on Automobile Accidents.—The Kansas Medical Society has appointed a committee on automobile accidents with the following members: Drs. Arthur K. Owen, chairman; John L. Lattimore, Harold W. Powers and Fred P. Helm, all of Topeka.

Personal.—Dr. Henry A. Dykes, Wichita, has retired as chief medical officer of the Veterans Administration Facility in Wichita after holding the position seventeen years; he will be succeeded by Dr. George E. Tooley.—Drs. Ova P. Davis and William L. Warriner, Topeka, were guests of honor at a banquet given by the Shawnee County Medical Society in Topeka recently in recognition of their completion of forty years in the

practice of medicine.—Dr. Roy B. Weathered, Kansas City, Mo., will succeed Dr. Lawrence F. Steffen, El Dorado, as health officer of Butler County.—Dr. Samuel M. Hibbard has been elected mayor of Sabetha.

MASSACHUSETTS

Society News.—Dr. George W. Morse, Boston, was recently elected president of the Massachusetts Society of Examining Physicians and Dr. Matthew Norton vice president. Drs. Robert C. Gwin and William Pearce Coues, Brookline, were reelected treasurer and secretary respectively.

Personal.—Dr. Elliott P. Joslin, Boston, will deliver the two Malthus lectures and conduct a clinic in Oslo, Norway, September 5-7; he will also participate in a symposium on protamine insulin with Dr. H. C. Hagedorn, Copenhagen, and Dr. Wilhelm Falta, Vienna, before the Gesellschaft für Verdauungs- und Stoffwechsel-Krankheiten in Stuttgart September 23.

Resolution Opposes Exclusion of Nonmedical Workers as Health Officers.—At a meeting of the Massachusetts Public Health Association June 30 a resolution was adopted recording its opposition to the report of the National Health Officers Qualifying Board to the United States Conference of Mayors so far as it excludes properly trained and otherwise qualified nonmedical public health workers from serving as health officers. The resolution points out that public health work is not limited exclusively to medical subjects and knowledge but is inextricably dependent on engineering, bacteriology, chemistry, physics, sanitation, vital statistics, nutrition, public health education and other highly scientific but nonmedical pursuits. The resolution is based on the report published in the *American Journal of Public Health*, January 1938, recommending that only physicians shall be eligible to serve as health officers in American cities.

MICHIGAN

Change in Speakers at State Meeting.—Dr. William S. Sadler, Chicago, will address the county secretaries' conference September 20 during the annual meeting of the Michigan State Medical Society in Detroit. His subject will be "The Grand Opportunity for Leadership by the County Medical Society." Dr. Harrison H. Shoulders, Nashville, Tenn., speaker of the House of Delegates of the American Medical Association, who was originally scheduled to address the conference, is unable to attend.

Graduate Course in Internal Medicine.—Wayne University College of Medicine and Receiving Hospital, Detroit, will offer a graduate course in internal medicine September 12-17. Two hours daily will be devoted to bedside diagnosis and treatment. Ward rounds will be conducted with groups of from four to six persons so that each physician will have the opportunity to examine every patient. Lectures on recent advances in therapeutics will also be included. Any licensed physician may enroll in the course.

Personal.—Dr. Russell E. Pleune, Lansing, formerly in charge of the bureau of venereal disease control for the state department of public health, has been named director of the Dickinson County health unit, effective September 1; he succeeds Dr. Clifton E. Merritt.—Dr. Christopher J. Stringer, Detroit, has been appointed superintendent and medical director of the Ingham Tuberculosis Sanatorium, Lansing, succeeding Dr. George C. Stucky, who had held the position since 1925. Dr. Stucky has been appointed director of the Eaton County Health Department, effective September 1; he fills the vacancy left when Dr. Thomas E. Gibson, Paw Paw, resigned to accept a similar position in Van Buren County.—Dr. Fred R. Hanna has been appointed superintendent of the State Home for the Feeble-minded at Lapeer; he has been acting superintendent at the institution since May 1937.

MINNESOTA

Chiropractor Jailed—Abortions.—Herman V. Feenstra, 65, an itinerant unlicensed chiropractor, was sentenced by Judge Joseph Moriarty, Shakopee, August 10, to a four year term in prison, according to the state board of medical examiners. Following his arrest August 8 Feenstra pleaded guilty to a charge of performing illegal operations. According to the board, Feenstra stated he was born at Ackley, Iowa, and that he graduated from the Davenport School of Chiropractic in 1922. He located at Elkton, S. D., but lost his license when he became involved in illegal practices. He was convicted in South Dakota on an abortion charge and was arrested for

manslaughter, drunken driving and rape. The clerk in Brookings stated that Feenstra jumped a \$2,500 cash bond January 19 in the rape case. When apprehended, Feenstra had two grips in his car containing instruments for performing abortions. His records indicate that he has performed hundreds of these operations, charging from \$15 to \$300 per patient, the board stated.

MISSISSIPPI

Health Officers' Conference.—A meeting of county health officers was scheduled to be held in Jackson August 8-9. The theme of the session was the control of syphilis, and the speakers included Drs. Felix J. Underwood, state health director; Archie L. Gray, state director of communicable disease control; Dolph V. Galloway, Meridian; Henry V. Ricks, John A. Milne, Jackson; Alton R. Perry, Laurel; Andrew Hedmeg, Natchez; Martin T. Van Studdiford, New Orleans; Charles R. Gillespie, Indianapolis; Robert H. Dejarnette, Rolling Fork, and W. E. Noblin, Jackson.

NEW JERSEY

Conference for County Society Officers.—The Medical Society of New Jersey has invited officers of county medical societies to meet in Trenton September 11 for a "training conference." Following a luncheon there will be first a combined conference of all officers and later separate conferences, one for presidents and vice presidents and another for secretaries, historians and reporters. Among the subjects to be included will be county society committees, county society membership, survey of medical needs and supplies, the art of presiding, county society bulletins and activities of the state society.

Institute for Medical Research.—The Squibb Institute for Medical Research "to create in the medical and biological fields an industry-supported research enterprise" has been organized by E. R. Squibb and Sons at New Brunswick with a new laboratory building recently completed at a cost of \$750,000. Dr. George A. Harrop, formerly associate professor of medicine, Johns Hopkins University School of Medicine, Baltimore, will be director of research in direct charge of the institute and in addition will head the division of experimental medicine. There will be three other main divisions and in addition there will be a biochemical laboratory and a medicinal chemistry laboratory. Dr. Harry B. Van Dyke, professor of pharmacology, Peiping Union Medical College, Peiping, China, will be head of the division of pharmacology; Dr. Geoffrey W. Rake, former research associate in the Connaught Laboratories, University of Toronto, the division of bacteriology and virus diseases, and Erhard Fernholz, formerly of Princeton University, the division of organic chemistry. Hans Jensen, Ph.D., formerly of the laboratory of endocrine research, Johns Hopkins University, Baltimore, will be in charge of the biochemical laboratory, and William A. Lott, M.S., who has been head of Squibb's research group since 1926, in charge of the laboratory of medicinal chemistry. Other appointments are as follows:

Roy O. Greep, Ph.D., formerly instructor at Harvard University, Cambridge, Mass., and Bacon F. Chow, Ph.D., associate professor of biochemistry, Peiping Union Medical College, Peiping, China, to the division of pharmacology.

Arthur E. O. Menzel, Ph.D., instructor in biologic chemistry, Columbia University, New York, and Morris F. Shaffer, Ph.D., assistant in bacteriology, Harvard, to the division of bacteriology and virus diseases.

Homer E. Staveland, Ph.D., formerly research fellow in chemistry, Yale University, New Haven, Conn., and Harold B. MacPhillamy, a graduate student in the department of organic chemistry, Columbia University, New York, to the division of organic chemistry.

Sybil Tolksdorf, recently engaged in research at the Institute of Experimental Biology, University of California, associate in the biochemical laboratory.

Frank H. Bergelme and David F. Menard, Ph.D., members of the Squibb staff, associate and assistant respectively in the laboratory of medicinal chemistry.

Stefan Ansbacher, D.Sc., of the Squibb staff since 1937, associate in the division of experimental medicine.

The division of experimental medicine is working out a plan of hospital affiliation to provide clinical facilities. A ward of fifteen or twenty beds will be maintained for the observation of patients in connection with research problems at the institute. Under the direction of this division, new fellowships in medical schools will be established and existing fellowships will be continued as part of the institute's program. Dr. Harrop, a native of Illinois, graduated in 1916 from Johns Hopkins' medical school and was a member of the faculty from 1924 to 1937. The new laboratory building will be dedicated early in October.

NEW YORK

Conference on Problems of Rural Medicine.—A conference on the problems of rural medicine sponsored by the staff of the Mary Imogene Bassett Hospital, Cooperstown, will meet October 7-8. The subjects to be considered are rural morbidity and public health programs in rural areas; postgraduate medical education in rural areas and the economics of rural medicine, including the rural hospital, the rural physician and the member of a rural community. The advisory committee for the conference consists of Drs. Marion A. Blankenhorn, Cincinnati; Frank G. Boudreau, executive director, the Milbank Fund, New York; Thomas P. Farmer, Syracuse, chairman of the council committee on graduate education, Medical Society of the State of New York; Edward S. Godfrey Jr., state health commissioner, Albany; Harry S. Mustard, professor of preventive medicine, New York; Willard C. Rappleye, dean, College of Physicians and Surgeons, Columbia University, New York; Ray Lyman Wilbur, president of Stanford University; Mr. Dan D. Casement, Juniata Farm, Manhattan, Kan.; Michael M. Davis, Ph.D., chairman, committee on research in medical economics, New York; Louis I. Dublin, Ph.D., third vice president, Metropolitan Life Insurance Company, New York; Lowell J. Reed, Ph.D., dean, Johns Hopkins University School of Hygiene and Public Health, Baltimore, and Mr. Owen D. Young, chairman of the board of the General Electric Company, New York.

New York City

Hospital News.—A new x-ray department was recently dedicated at Long Island College Hospital, Brooklyn, with Dr. Francis Carter Wood as the principal speaker at the ceremony. The new department, which cost \$67,000, includes a 400,000 volt roentgen therapy machine and is under the direction of Dr. Alfred L. L. Bell. It is named in honor of the late Albert L. Mason, a former president of the hospital.

Psychologic Clinic for Policemen.—The Patrolmen's Benevolent Association has established a psychologic clinic for policemen in difficulties, with a policeman-psychologist in charge. The New York Times reports that the clinic is an effort to prevent suicide among the men because of personal troubles. The principal causes of suicide listed are carrying life insurance beyond income allowance, buying furniture and other possessions on credit, helping needy relatives, acting as endorser for friends and relatives who fail to repay loans, gambling in the hope of paying off debts, buying too expensive a home, running up large medical bills instead of first seeking the advice of the police surgeon, entertaining beyond means, and keeping children in private schools. Plans have been made for the assistance of psychiatrists in psychiatric cases.

WPA Workers Withdrawn from Hospitals.—Assignments of 3,289 WPA workers in the twenty-six city hospitals were to be ended August 27 on an order from Washington closing the hospital project, the New York Times reported August 18. The order stated that employment of relief workers in jobs that should be included in the city budget could no longer be sanctioned. During the five years since the first relief workers were brought into the department their duties have come to overlap many of those of the regular employees, according to Dr. Sigismund S. Goldwater, hospital commissioner; he estimated that replacements would have to be found for at least 35 per cent of them, although the condition of city finances gave little hope of additional funds. According to WPA officials, the project saved the department of hospitals about a million dollars a year.

NORTH CAROLINA

Deaths from Tetanus Increase.—Seven deaths from tetanus occurred in North Carolina during July, bringing the total of deaths for the year to twenty-three as compared with twenty-one for the entire year 1937 and twenty-nine for 1936.

Society News.—The Buncombe County Medical Society was addressed August 1 by Dr. Karl Schaffie, Asheville, on "The Value of Inspection in Physical Diagnosis."—Dr. Lewis W. Elias, Asheville, recently addressed the Catawba Valley Medical Society on "Colitis in Children."

Personal.—Dr. Joseph Lindsay Cook, Winston-Salem, assistant county health officer and medical superintendent in charge of the Forsyth County Hospital, has resigned to take charge of a syphilis control program in Guilford County.—Dr. Henderson Irwin, Eureka, was honored with a supper by citizens of the community recently on his fifty-second birthday. Six hundred persons attended. He has been in Eureka twenty-five years.

Beauty Shop Workers Required to Have Wassermann Tests.—The North Carolina state board of cosmetic arts examiners has announced that all new applicants for licenses to work as "beauticians" who file for the next examination in October must present certificates showing that they have had Wassermann tests. In addition, the certificate will be required of all workers who henceforth apply for renewal of licenses. When such tests are positive, the examining board may require treatment before issuing the licenses. This action was taken following a conference with the state board of health, which is working out an extensive program for the control of venereal disease.

NORTH DAKOTA

Dr. Skelsey Secretary of State Society.—Dr. Albert W. Skelsey, Fargo, was reelected secretary of the North Dakota State Medical Association at the recent meeting. Dr. William W. Wood, Jamestown, is treasurer and not secretary, as stated in a news item in THE JOURNAL, August 20, page 728.

OHIO

Society News.—Dr. Harold H. Wagner, Dayton, addressed the Greene County Medical Society in July on "Vaginal Discharge: Its Diagnosis and Treatment."—Dr. John H. Skavlem, Cincinnati, addressed the Hempstead Academy of Medicine June 13 in Portsmouth on "Tuberculous and Nontuberculous Chronic Lung Infections."

Promotions at Cleveland.—Among promotions on the faculty of Western Reserve University School of Medicine, Cleveland, recently announced were the following:

- Dr. Harold Feil, associate clinical professor of medicine.
- Dr. Donald M. Glover, associate clinical professor of surgery.
- Dr. Robert L. Faulkner, assistant professor of gynecology.
- Dr. Edward H. Cushing, assistant clinical professor of medicine.
- Dr. Harry Hauser, assistant professor of roentgenology.
- Dr. William C. McCally, assistant clinical professor of surgery.
- Dr. Paul G. Moore, assistant clinical professor of ophthalmology.
- Dr. Michael Paul Motto, assistant clinical professor of ophthalmology.
- Dr. Harley A. Williams, assistant clinical professor of medicine.

OREGON

New Tuberculosis Hospital.—An allotment of \$90,000 from PWA funds, combined with an appropriation by the state legislature, has assured construction of a new hospital for tuberculosis, probably to be located on the campus of the University of Oregon Medical School, Portland. This will be the third state hospital for tuberculous patients.

PENNSYLVANIA

Personal.—The Ex-Residents Association of the Harrisburg Hospital at its recent annual reunion honored Dr. John B. McAlister with a dinner celebrating the fiftieth anniversary of his internship. Judge John E. Fox of the Dauphin County Court served as toastmaster and the speakers were Drs. Henry D. Jump and David Riesman, Philadelphia; James M. H. Rowland, Baltimore, and Henry W. A. Hanson, D.D., president of Gettysburg College, Gettysburg. Dr. McAlister graduated from the University of Pennsylvania School of Medicine in 1887.

TENNESSEE

Changes in Health Officers.—Dr. W. T. Rainey, formerly of Brownsville, has been appointed health officer of Lake County, succeeding Dr. James P. Moon, Tiptonville, who, it is reported, will become a member of the unit in Dyer County. Dr. Earl P. Bowerman, Trenton, has been named health officer of Gibson County. Dr. J. W. Erwin, Savannah, health officer of Hardin County, has been appointed health officer of Giles County to succeed Dr. Wilfred N. Sisk, Pulaski, who went to Johns Hopkins University School of Medicine, Baltimore, for a course in venereal diseases.

TEXAS

Personal.—The Tarrant County Medical Society gave a barbecue and picnic recently in honor of Dr. Leopold H. Reeves, Fort Worth, president-elect of the Texas State Medical Association, at the Lake Worth home of Dr. Thomas B. Bond. Dr. Robert G. Baker, Fort Worth, presided; Drs. Ernst W. Bertner, Houston, president of the state association, and John H. McLean, Fort Worth, made addresses and Dr. Caleb O. Terrell, Fort Worth, on behalf of the society, presented a traveling bag to Dr. Reeves.

Society News.—The Texas Club of Internists will visit Cleveland September 6-10. A program will be presented September 6-7 at the Cleveland Clinic and September 8-10 at the Lakeside Hospital and Western Reserve University School of

Medicine.—Drs. William I. Southerland and George K. Stephens Jr., Sherman, addressed the Grayson County Medical Society, Sherman, June 14, on "Diagnosis of Heart Disease" and "Abdominal Pains in Children" respectively.—Dr. Frank Smith Hale, Houston, addressed the Jefferson County Medical Society, Port Arthur, in June on "Hydatid Mole and Chorio-Epithelioma."—At a meeting of the Taylor-Jones Counties Medical Society, Abilene, June 14, Dr. Victor E. Schulze, San Angelo, spoke on "Problems in Diabetes."—Drs. Martin H. Benson and Pauline A. Miller, Lubbock, addressed the Lubbock-Crosby Counties Medical Society in Lubbock June 7 on "Parenteral Infections Causing Diarrhea in Infants" and "Diarrhea in Infants and Young Children" respectively.

UTAH

Committee on Industrial Health.—The council of the Utah State Medical Association appointed a committee on industrial health, July 25, consisting of Drs. Oza J. LaBarge, chairman, Salt Lake City; Paul S. Richards, Bingham Canyon, and John R. Anderson, Springville.

WASHINGTON

Fraternal Order Seeks to Coerce Physicians.—At a recent state convention of the Fraternal Order of Eagles, a resolution was adopted providing that committees will call on representatives of medical organizations throughout the state to learn whether or not they will allow their members to act as physicians for the local Eagle organizations. If this procedure is disapproved by the medical societies, it is expected that the Eagles will vigorously support measures for socialization of medicine, *Northwest Medicine* reports.

WEST VIRGINIA

Changes in State Health Department.—Dr. Albert M. Price, Charleston, formerly director of county health work in the state department of health, has been appointed collaborating epidemiologist and director of the division of communicable diseases. Dr. Thomas H. Blake, Charleston, director of the division of maternal and child hygiene, succeeded Dr. Price in the county health work and Dr. Thomas W. Nale, Charleston, assistant to Dr. Blake, succeeded him.

Society News.—Dr. James R. Bloss, Huntington, addressed the Cabell County Medical Society, Huntington, July 21, on "Some Phases of Medical Economics."—Drs. Charles E. Conrad, Harrisonburg, Va., and Orlando S. Reynolds, Franklin, addressed the Potomac Valley Medical Society at a meeting at Thorn Spring Park near Franklin June 23 on "Pediatric Problems of Special Interest to the Practicing Physician" and "Analgesia in Labor" respectively.—Dr. Joseph H. Barach, Pittsburgh, addressed the Wetzel County Medical Society, New Martinsville, June 30, on "A Scientific Approach to the Treatment of Diabetes."

Kanawha Society Opposes Regimentation of Physicians.—The Kanawha Medical Society through its executive board has recorded its opposition "to any and all plans which may be presented to the congress of these United States for enactment into law which will tend toward the regimentation of the physician or the patient." A resolution expressing disapproval of the plan of action outlined at the National Health Conference at Washington, D. C., July 18-20, was adopted at a recent meeting. The resolution also reaffirmed "the traditional spirit of willingness of our profession to continue to do freely and well all proper charity work which comes to us."

WISCONSIN

Personal.—Dr. Benjamin Lieberman has resigned as director of school hygiene in the Milwaukee Health Department to become director of health service at the Milwaukee State Teachers' College.—Dr. Joseph F. Smith, Wausau, received an engraved plaque as a gift from the Ninth Councilor District Medical Society commemorating twenty-five years of service as the society's secretary. The plaque was presented at the summer meeting June 30 in Marshfield.

District Meetings.—At the annual meeting of the Fifth Councilor District Medical Society in Sheboygan June 30 the speakers were Drs. Paul B. Magnuson, Chicago, on medical and surgical treatment of arthritis; William F. Lorenz, Madison, on blood tests for syphilis; Walter Schiller, Chicago, cancer of the cervix, and Cleveland J. White, Chicago, who held a clinic on diseases of the skin. Drs. Willard O. Thompson, Chicago, and George R. Dunn, Minneapolis, addressed the Ninth Councilor District Medical Society June 30 on "Practical Phases of Endocrine Treatment" and "Treatment of Fractures" respectively.

HAWAII

Society News.—Dr. Wilhelm Dressler, Vienna, recently lectured before the Honolulu County Medical Society on clinical cardiology, elementary and advanced electrocardiography. Dr. Albert Graeme Mitchell, Cincinnati, gave a series of refresher lectures on pediatrics under a maternal and infant hygiene program of the territorial board of health, speaking on the islands of Hawaii, Maui and Kauai as well as in Honolulu. Dr. Bruce H. Douglas, Detroit, has been in the islands during the summer making a survey of the tuberculosis situation.

GENERAL

Medicolegal Conference.—The Massachusetts Medicolegal Society is sponsoring a two day conference to be held October 4-5. Physicians and lawyers interested in medicolegal work are invited to attend; registration will be requested although no fee will be charged. The tentative program covers technic and demonstrations of postmortem examinations, discussion and demonstrations of such topics as identification, finger prints, ballistics and medicolegal chemical tests, and lectures on medicolegal laws and procedures and the physician as a medical expert. Dr. William H. Watters, 270 Commonwealth Avenue, Boston, is chairman of the committee in charge of arrangements.

Fellowships in Psychiatry.—The National Committee for Mental Hygiene announces a group of appointments for one year's training in extramural psychiatry. Under a grant from the Commonwealth Fund the following have been appointed:

Dr. Grace E. McLean, Pilgrim State Hospital, Brentwood, N. Y., to the Cleveland Child Guidance Clinic.
Dr. John A. Rose, Cornell University Student Health Service, to the Philadelphia Child Guidance Clinic.
Dr. John Russell, Osawatimie (Kan.) State Hospital, to the Los Angeles Child Guidance Clinic.
Dr. Rex E. Buxton, Iowa State Psychopathic Hospital, Iowa City, to the Judge Baker Guidance Center, Boston.
Dr. William B. Curtis, Bellevue Hospital, New York, to the Mental Hygiene Clinic, New York.

Under local provision Dr. William L. Holt Jr., Worcester State Hospital, Worcester, Mass., was assigned to its child guidance clinic and Dr. Norman Westlund, Traverse City (Mich.) State Hospital, to the Children's Center, Detroit.

Award in Industrial Medicine.—At the annual meeting of the American Association of Industrial Physicians and Surgeons in Chicago in June, announcement was made of the establishment of the W. S. Knudsen Award "for the most outstanding contribution to industrial medicine." The award, a bronze plaque, is the gift of William S. Knudsen, president of General Motors Corporation, and members of the committee on award of the association include Drs. Loyal A. Shoudy, chief of medical service, Bethlehem Steel Company, Bethlehem, Pa., chairman; McIver Woody, medical director, Standard Oil Company, New York, and Clare F. N. Schram, Kingsport, medical director, Tennessee Eastman Corporation. The first award will be presented at the association's annual meeting in 1939.

Bequests and Donations.—The following bequests and donations have recently been announced:

Mount Sinai Hospital, New York, \$10,000 at termination of a trust established in the will of the late Mrs. Tessie K. Frank.
Roosevelt Hospital, New York, \$5,000 by the will of the late Mrs. Elizabeth Newcomb.
Mount Sinai Hospital, Philadelphia, \$1,000 by the will of the late Jacob Notkin.
St. Agnes Hospital, Philadelphia, \$500 from the estate of the late Dr. John J. Fralinger to maintain a bed for needy persons.
Jewish Hospital, Brooklyn, \$5,000 by the will of the late Simon F. Rothschild.
Michael Reese Hospital, Chicago, \$15,000 by the will of Dr. Emanuel Friend. At the termination of several trusts the hospital will receive funds for a convalescent home; if it does not accept the home the funds will go to the Albert Merritt Billings Hospital, Chicago.
Jefferson Medical College, Philadelphia, will be the final beneficiary of a trust fund of \$60,000 created by the late Dr. Warren C. Batroff.
Mount Sinai Hospital, New York, \$50,000; Beckman Street Hospital, New York, \$5,000 by the will of the late Joseph F. Cullman.
Jewish Hospital, Brooklyn, \$15,000, and Lenox Hill Hospital, \$1,000 by the will of Mrs. Rose Abraham.

Association for Study of Neoplastic Diseases.—The annual meeting of the American Association for the Study of Neoplastic Diseases will be held at the Mayflower Hotel, Washington, D. C., September 8-10. The meeting will be mainly a lantern slide and x-ray film demonstration. Sessions will be devoted to the following subjects: lesions of the stomach, colon and rectum, under the chairmanship of Dr. George A. Stewart, Baltimore; lesions of the pancreas and small intestine, Dr. Janvier W. Lindsay, Washington, D. C.; endocrinology as related to neoplasia, Dr. Charles F. Geschickter, Baltimore; lesions of the oral cavity, larynx, trachea and lungs, Dr. George R. Moffitt, Harrisburg, Pa.; mediastinal

and retroperitoneal tumors, Dr. Louisa E. Keasbey, Lancaster, Pa.; lesions of the breast, Dr. John Shelton Horsley, Richmond, Va., and lesions of the bones, Dr. Ralph E. Myers, Oklahoma City. Dr. Leopold Clarence Cohn, Baltimore, is president of the association and Dr. Eugene R. Whitmore, Washington, secretary.

Southern Tuberculosis Meeting.—The annual meeting of the Southern Tuberculosis Conference and Southern Sanatorium Association will be held in Louisville, Ky., at the Brown Hotel September 19-21. There will be medical and nonmedical sections as well as general sessions. Among the medical speakers will be:

Dr. Frederick T. Lord, Boston, Certain Aspects of the Program in Massachusetts for the Prevention and Control of Tuberculosis.
Dr. James Burns Amberson Jr., New York, The Future Possibilities of the Tuberculosis Problem.
Dr. Porter P. Vinson, Richmond, Va., Tuberculous Tracheobronchitis.
Dr. John Alexander, Ann Arbor, Mich., Role of Lobectomy and Pneumonectomy in Bronchiectasis and Carcinoma of the Lung.
Dr. Kendall Emerson, New York, The Responsibility of the National Tuberculosis Association for State and Local Programs.

At the conference banquet Monday night the speakers will be Drs. Henry Chesley Bush, Livermore, Calif., president of the National Tuberculosis Association; Henry G. Reynolds, Paducah, Ky., president of the Kentucky State Medical Association, and Arthur T. McCormack, Louisville, president of the American Public Health Association. Dr. Paul H. Ringer, Asheville, N. C., is president of the conference and Dr. Jesse D. Riley, State Sanatorium, Ark., of the sanatorium association.

Obstetricians, Gynecologists and Abdominal Surgeons.—The fifty-first annual meeting of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons will be held at the Greenbrier Hotel, White Sulphur Springs, W. Va., September 22-24. Among the speakers will be:

Dr. Otto S. Krebs, St. Louis, Sterility Studies.
Dr. Albert Mathieu, Portland, Ore., Recent Developments in Diagnosis and Treatment of Hydatidiform Mole and Chorio-Epithelioma.
Dr. Emil Novak, Baltimore, Clinical Syndromes Referable to Disorders of Ovulation.
Dr. Emmett D. Colvin, Atlanta, Ga., Behavior of Basal Metabolism in the Course of Developing Toxemia of Pregnancy: Correlation with Placental Infarcts and Other Significant Findings.
Dr. Thomas R. Goethals, Boston, Management of Breech Delivery in Primiparae.
Dr. John C. Hirst, Philadelphia, Maternal and Fetal Expectations with Multiple Pregnancy.
Dr. Jacob P. Greenhill, Chicago, Increased Incidence of Fetal Abnormalities in Cases of Placenta Praevia.
Drs. Virgil S. Counseller and Nelson W. Barker, Rochester, Minn., Postoperative Thrombophlebitis: Prevention and Treatment.

The Joseph Price Oration will be delivered by Dr. Charles Burger, professor of obstetrics and gynecology, University of Budapest, Hungary. Dr. Paul Titus, Pittsburgh, president of the association, will give his official address on "Obstetrics and Gynecology as a United Specialty."

Government Services

Health Activities Under Social Security Act

The U. S. Public Health Service recently issued a summary of its activities during the three years since the Social Security Act became a new law, providing an annual appropriation of \$8,000,000 for the development of public health work.

Nearly 3,000 persons had received postgraduate training in public health work up to June 30, 1937, and 1,300 more have been in training in 1938. They include 651 medical officers, 162 engineers, 1,540 nurses, 451 sanitation officers, eighty-eight laboratory workers and sixty others. More than 200 medical officers had had a full year's course in public health administration. Public health nurses employed by local and state agencies increased from 16,000 to 18,000. State health departments employed 322 health nursing administrators, supervisors and consultants in 1937, compared with 149 in 1931. Six states are completely covered by full-time health officers; in some states several counties are combined into districts.

Through grants-in-aid to states, a number of specialized health activities have been developed as separate divisions of state health departments. By July 1, 1937, twenty-four states had separate divisions for venereal disease control compared with thirteen before the new law; thirty had full time and two part time officers for venereal disease control. Fifteen states now have separate divisions for industrial hygiene, compared with three prior to Jan. 1, 1936. Other separate divisions have been set up for local health administration, public health nursing, maternal and child health, dental hygiene, public health education, engineering, tuberculosis, cancer control, laboratories, malaria control and rodent plague control.

New Sources of Ephedrine

Ephedrine is obtained from herbs which grow wild in China and in Spain. No ephedrine has been obtained from Spain since the civil war began, and the small district of China in which the herb grows was the scene of hostilities in the early part of the Japanese invasion, so that even the part of the crop which was not trodden under foot by the troops could not be collected. The result was that the price of ephedrine soared and a famine was threatened; but this has been averted in the following way. The drug was produced synthetically in Europe and an Indian herb which also is a source of ephedrine but had been rejected by the manufacturers because its content of ephedrine was far below that of the Chinese herb is being used. London dealers are eager to buy the Indian herb, which previously was fed to pigs. The result is that the price of ephedrine has dropped from four times the normal to only 25 per cent above it. The experimental cultivation of the herb has been begun in the British colony of Kenya by means of material supplied from the Kew botanical gardens. The cost of producing ephedrine synthetically is stated to be well above the market price of the natural product when the Chinese plant is available.

The Fight Against Cancer

At a meeting of the British Empire Cancer Campaign, Sir Arthur MacNalty, chief medical officer of the Ministry of Health, stated that 65,000 deaths took place annually from cancer. It had now taken the second place in the list of fatal diseases in this country. From the beginning of our national records of mortality each year had shown, almost without exception, a rise in the number of deaths from this cause. The increasing longevity of the population was an important factor, since the mortality from cancer was greater at the higher ages. Today people lived on the average fifteen years more than they did a generation ago. The ability to diagnose cancer in difficult cases had been steadily improving. The highly complex study of the causes of cancer was being carried on with great vigor throughout the world and British scientists were contributing their full share. In diagnosis and treatment the outlook was brighter than it was. In Great Britain twenty-two radium centers, which were specialized institutions both for diagnosis and for treatment, were established within recent years.

Lady Barrett (gynecologic surgeon) gave statistics of a London cancer clinic. Of patients with early cancer treated more than five years ago, 83 per cent were alive and well today. Patients treated later, when the disease was more advanced, gave a figure of 65 per cent. Of all the patients treated, 35 per cent were alive at the end of five years. These figures showed that if patients could be induced to seek treatment in the early stage there was a very good hope of complete cure.

Hospitals for Air Raid Casualties

The Ministry of Health is working out comprehensive plans for the hospital accommodation of air raid casualties and has issued a circular to the local authorities to the effect that every hospital must be prepared to deal with air raid casualties occurring in its immediate neighborhood. Also every hospital which is not in a specially dangerous position will be expected to receive both casualties and ordinary patients from dangerous areas. The plans which have been made would be put into

immediate operation in various parts of the country should the necessity arise. It is a shocking result of modern warfare that hospitals, formerly a refuge for the wounded, should now themselves be a dangerous place for them.

PARIS

(From Our Regular Correspondent)

July 30, 1938.

Chair of Endocrinology in Collège de France

The Collège de France is an institution devoted chiefly to research in medicine and all other branches of science. Some of the most eminent men in France have been members of its faculty, which is independent of the Faculté de médecine, although both organizations form part of the University of Paris. The minister of public education has just announced the creation of a chair of endocrinology in the Collège de France and has appointed as its first occupant Professor Courier of Algiers, whose investigation of the biology of the female sex hormones in their relation to the hypophysis in 1937 was of great interest.

Two Eminent Teachers Become Emeritus Professors

The law which now requires the retirement of university professors at the age of 65 was modified several years ago in favor of some distinguished members of French faculties of medicine so that they would not be obliged to retire until they had reached the age of 70. This prolongation of the age of retirement enabled two Paris clinicians, well known all over the world, to continue their teaching activities until the end of the 1937-1938 school year. The two professors who have now reached the age limit are Professor Bezançon, phthisiologist and Professor Marion, urologist. The clinics of these two teachers have been visited by many American specialists.

Sulfanilamide Treatment of Streptococcic Meningitis

Three papers were read at the June 17 meeting of the Société médicale des hôpitaux of Paris in which ten cases of streptococcic meningitis successfully treated with sulfanilamide were reported. In the first paper Dr. Brulé and his associates reported a case of acute optochiasmatic arachnoiditis with streptococcic meningitis, which had developed after the lesion of suppurative tonsillitis had evacuated its contents spontaneously about three weeks before the patient's admission to the hospital. During the first stage the only complaint was a severe headache. There was a slight rise of temperature, but ocular examination revealed the typical appearances of acute optochiasmatic arachnoiditis secondary to the tonsillar infection. At this time lumbar puncture showed 240 leukocytes per cubic millimeter. In the second stage (three days after admission) the symptoms and signs of diffuse meningitis became marked. Cultures of the fluid obtained by lumbar puncture showed the causative organism to be the hemolytic streptococcus. Sulfanilamide was immediately given, 65 Gm. by mouth and three intraspinal injections of 0.2 Gm. over a period of twenty-eight days. The authors expressed the opinion that the intraspinal method of administration had been more efficacious than the oral method. During the third stage a marked improvement of the arachnoiditis was noted. This is unusual, because as a rule this condition ends in complete loss of sight.

The second paper was by Dr. René Martin of the Institut Pasteur, who stated that the mortality rate of streptococcic meningitis had until recently been 97 per cent. He had given sulfanilamide to three children with the disease, all of whom recovered. In addition to these three children observed at the Institut Pasteur, three others with streptococcic meningitis of otitic origin had been successfully treated with sulfanilamide. The drug should be given in large doses and the administration continued for at least several weeks after apparent recovery to

prevent recurrences. During the first few days sulfanilamide is given both by mouth and intraspinally. For oral administration, adults are given from 8 to 10 Gm. and children 0.15 Gm. daily per kilogram of weight. On account of rapid elimination of the drug, it is advisable to give it every two hours during the day and every three hours during the night. It is given intraspinally during the first days of the illness. After from 10 to 20 cc. of spinal fluid, according to the age of the patient, has been withdrawn, an equal quantity of an 0.85 per cent solution of sulfanilamide, previously heated to body temperature on a water bath, is injected. The doses for intraspinal use are increased or decreased according to whether the concentration of the sulfanilamide in the spinal fluid is superior or inferior to 4 mg. per hundred cubic centimeters of the cerebrospinal fluid. The higher the concentration, the more rapidly does recovery take place. The permeability of the meninges toward sulfanilamide varies with each patient; hence the necessity of adjusting the doses for intraspinal use according to the concentration of sulfanilamide in the cerebrospinal fluid. Dr. Martin expressed the opinion that the administration of sulfanilamide by the intraspinal route was the chief factor in the success of the treatment in his cases of streptococcic meningitis.

The third report was submitted by Prof. Robert Debré and his associates. Before using sulfanilamide, they had observed twenty similar cases of meningitis with but one recovery. The three patients to whom they gave sulfanilamide were children 6, 4 and 9 years old and in all the meningitis was of otitic origin. These authors employed both the oral and the intraspinal method of giving the drug. For oral administration, doses as high as from 3 to 5 Gm. daily must be given even to children, and they must continue to be given for three weeks after apparent recovery. For intraspinal administration they used an 0.85 per cent solution, of which a minimum of 15 cc. should be injected if the concentration of sulfanilamide in the spinal fluid is not inferior to 4 mg. per hundred cubic centimeters. When this concentration is reached or when the spinal fluid is sterile and contains very few leukocytes, the intraspinal method is discontinued. The spinal fluid became sterile within forty-eight hours after the beginning of treatment. The complications noted, so far as the effects of the drug are concerned, were cyanosis, at times very marked at the onset but decreasing noticeably even though use of the drug was continued, a rather persistent cough and in one case a drop in the red cell count to 1,730,000.

BERLIN

Blindness Defined

The National League for Industrial Employment of the Blind has established, with governmental approval, certain practical definitions of blindness, designed to facilitate classification of virtually blind persons. In addition to the totally blind, all persons are considered as blind whose central visual acuity amounts to from one fiftieth to one twenty-fifth of the normal (although most persons of the latter group are able to find their way about the streets without the help of others). Practical blindness may also be considered present even if the visual acuity is greater than one twenty-fifth of normal, in special cases, as for example if a depreciated acuity of vision is accompanied by considerable diminution of the visual field. The latter class is composed chiefly of patients who present certain disorders: optic atrophy, glaucoma, pigmental degeneration, retinal detachment, hemianopia. Further particular conditions in which blindness may be assumed are nystagmus with phantom movements of external objects perceived, nyctalopia following pathologic changes of the inner eye, and finally cases in which a full practical evaluation of central visual acuity is qualified by the advanced age of the patient.

Child Labor and the Protection of Youth

New legislation to regulate child labor and the working hours of adolescents went into effect April 30. The new statute, which bears the title "Youth Protection Law," embodies the following principles: Child labor is generally forbidden. The adolescent worker is protected by a curtailment of working hours and prohibition of such night work as would make excessive demands. Sufficient leisure time is assured for further vocational training, physical exercise, development of character and national political education. In addition it is provided that the adolescent worker shall have vacations and that the latter may be purposefully utilized. Any person under the age of 14 is legally considered a child. Adolescents are defined as persons over 14 but under 18 years of age. Special regulations are envisaged which apply to certain occupational fields such as domestic service, agriculture in its various branches, fishing, maritime and inland navigation, and aviation.

It was difficult to formulate a legal definition of "work," but a clear understanding of what is meant by the term is particularly important with relation to child labor. Accordingly the new law concerns not only occupation in the apprentice relationship or in the employee relationship but also those services which resemble such relationships. To avoid difficulties, it is stipulated that school children 12 years old and over may be employed at light tasks in commercial establishments and act as errand runners and as assistants in sports. So-called family industries are not exempted from the provisions of the child labor laws, so the legal protection of the child extends into this sphere. Certain exceptions are allowed under state control. Children 12 years of age and over are permitted to work under the strictest state supervision and a precise record of the hours put in is kept on a special time card. This procedure is followed even if only one child is involved. This authorized employment of children is restricted as follows: The work period must not exceed two hours daily during the school year or four hours daily during vacation. Working hours must lie between 8 a. m. and 7 p. m. but not prior to morning school hours. Time required for traveling to and from work must fall within the stipulated time limits, namely must not extend beyond 7 p. m. The law further guarantees an uninterrupted free period of at least two hours following morning school hours and a similar period of at least one hour following afternoon school hours. During school vacations the child must be permitted at least fifteen days, consecutive if possible, of absolute freedom from work. Children may not work on Sundays and holidays excepting as helpers in sports. Children may perform only certain duties such as arrangement of merchandise, and delivery and messenger services. Exceptions are permitted in the theatrical and cinema industries. Special provisions govern infant entertainers under 3 years of age. Adolescent workers may work a maximal eight hour day and forty-eight hour week. Class hours in trade schools are reckoned as a part of working time. At the close of the working day an uninterrupted rest period of at least twelve hours must be assured. Certain rest periods are required if the working hours are long. Adolescents must not as a rule be employed at night work between the hours of 8 p. m. and 6 a. m. Certain exceptions are made in the case of employees of hotels, bakeries and the theatrical and allied industries. Other exceptions with regard to night work concern industries which are worked in shifts. Adolescent workers may no longer work after 2 p. m. on Saturdays, with certain exceptions; employees of transportation services, the food industry, hairdressing industry and so on. Now for the first time employers are compelled by law to provide adolescent workers vacations with pay. Accordingly, adolescents under the age of 16 are entitled to fifteen vacation days, workers from 16 to 17 years of age are entitled to twelve days or, if part of the time is spent in a Hitler Youth Camp or excur-

sion, to eighteen days. The new statute is implemented with extremely rigorous penalties for violation of its provisions. An unscrupulous employer who permits an employee under 18 years of age to risk serious endangerment of health from overwork is liable to a minimal jail sentence of three months.

BUENOS AIRES

(From Our Regular Correspondent)

July 30, 1938.

Department for Study of Allergic Diseases

A department for the study of allergic diseases, especially pollinosis, was organized some months ago in the Hospital Municipal de Vicente López in Buenos Aires. Dr. J. A. Bozzola, head of the department, made studies on the subject in the United States. He has recently made several studies on the subject in Argentina. He made determinations of the density of the pollen in the air in the various seasons of the year. He also studied the plants which produce pollen. The department has an office for consultations, a laboratory for the preparation of allergic extracts, and gardens for cultivation of plants to be used in preparing the extracts.

A new department for studies of allergic diseases is going to be opened in the near future in the Hospital de Clínicas of the Faculty of Medicine of Buenos Aires.

Rapid Diagnosis of Diphtheria

Dr. Alfredo Sordelli, head of the Instituto Bacteriológico del Departamento Nacional de Higiene, recently presented an interesting article of his collaborator Dr. Alfredo Mansullo to the members of the Academia Nacional de Medicina. The article deals with a method for the diagnosis of diphtheria by which the diphtheria bacillus can be cultured in three hours and a macroscopic and microscopic diagnosis of the colonies made at the same time. A mixture is prepared with 15 cc. of meat broth with peptone, 1.5 cc. of defibrinated ox blood and 1.5 cc. of a 2 per cent solution of potassium tellurite. The pharyngeal exudate is collected with a cotton swab and the latter is moistened with 2 cc. of the liquid mixture, placed in a test tube and left during three hours at a temperature of from 36 to 38 C. Small characteristic black colonies can be observed in the swab at the end of three hours, when the exudate contains diphtheric bacilli. Stained preparations, growths and inoculation of guinea pigs can be done with the black colonies. Carriers of diphtheria bacilli can be detected by the technic, which makes possible the examination of hundreds of children in a single forenoon. A still more rapid method consists in moistening the pseudo-membranes with a 2 per cent solution of sodium tellurite. Ten minutes later the throat is examined. When the exudate is diphtheric the membrane has become black or gray. The results of the method were compared with those of the cultural method in the department of diphtheria of the Muñiz Hospital. In most cases of diphtheria the results of the test were positive, whereas negative results were obtained in all cases in the absence of diphtheria.

Role of Adrenals in Hypophysial Diabetes

Investigations which have been carried on by Collip, Evans and Long have failed to produce hypophysial diabetes in normal animals. According to Houssay the failure is due to a lack of precaution, as the hypophysial glands have to be collected on solid carbon dioxide and the extracts have to be prepared and kept at a low temperature. Both the hypophysial glands and the extracts become inactive in a few hours if they are kept in a warm temperature. A hyperglycemia of from 0.15 to 0.38 per hundred cubic centimeters of blood which lasts all day may be obtained in from three to five days by using well prepared hypophysial extracts. Hyperglycemia diminished after injections of hypophysial extracts. Whenever it diminishes,

the administration of increased doses of the extract induces a new increase and later on a permanent diabetes, which persists after the injections are discontinued (Young). Houssay and his collaborators proved in 1929 and also by further studies on the subject that the resistance to insulin increases earlier than glycemia while the injections of hypophysial extracts are being given. The secretion of insulin by the pancreas is greatly diminished in animals with induced hypophysial diabetes. When diabetes of this type is permanent, the islands of Langerhans show degeneration. The theory concerning the part taken by the adrenals in transmitting the diabetogenic action of the anterior lobe of the hypophysis has been generally accepted since the reports by Long on the subject. Houssay and Biasotti in 1933 and in 1936 and Houssay and Leloir in 1935 found that the grafting of an anterior lobe of the hypophysis in toads without adrenals or pancreas and with or without a hypophysis intensifies attenuated diabetes. Houssay and Biasotti recently induced anterohypophysial diabetes in dogs. The animals were first deprived of an adrenal, then of the pancreas except for a remaining 4 Gm. of the structure, and at last of the remaining adrenal gland, after which an injection of the anterior lobe of the hypophysis was made in the peritoneum of the animals, which were maintained in the course of the experiment by means of certain doses of adrenal cortex extract, sodium citrate and sodium chloride. Hyperglycemia of 0.155, 0.175 and 0.25 was induced in dogs in this condition within three or four days of the administration of the anterohypophysial injection. Small doses of anterohypophysial extract which are not toxic may be used successfully after partial resection of the pancreas. The injections of adrenal cortex extract administered alone have no action. The results of these experiments show that the diabetogenic action of the anterior lobe of the hypophysis does not take place through the adrenals and that hypophysial diabetes can be induced in dogs which have previously been deprived of their adrenals. Adrenotrope extracts and prolactin fail to induce diabetes in dogs previously deprived of the hypophysis and of most of the pancreas. Dogs in the last mentioned condition have a normal glycemia. The administration of a dose of from 20 to 40 mg. of fresh anterior lobe of the hypophysis of bovine animals for each kilogram of body weight of the dogs induces hypophysial diabetes in the latter.

Health Insurance

Although there is still some anxiety among practitioners as to the effects of national insurance, the general excitement which accompanied the passage of the bill through parliament has passed, and it is now possible to review the situation more clearly. Some form of health insurance was inevitable for Australia. This country has not escaped the economic developments taking place all over the world and cannot remain blind to the fact that greater specialization in industry and the accumulation of capital in the hands of the big industrial concerns has reduced private production and greatly increased the number of wage earners in the community. Wages are cut to a minimum in the majority of cases, with the result that little provision can be made against the mischances of life or the financial stress occasioned by ill health. Unless medical services are to be put on a charitable basis, some form of compulsory insurance is necessary. At the same time "industrialization" is invading the medical field. The extensive knowledge and rapid development of medical science render specialization imperative. Moreover, overhead costs of an individual private practice, when viewed together with the decreased purchasing power of the greater part of the community, are fast becoming prohibitive. The practice of medicine is the most personal of the professions, and for this reason perhaps it has remained individual for so

long; but we have now reached a stage in the development of our society at which efficient service can best be achieved by a coordination of individual effort. Such a coordinated service is at present available to only a small section of the community.

Some reorganization of health services then is socially necessary; but whether the Australian government has provided this in the most desirable form, from the point of view either of the public or of the medical profession, is a debatable question. The bill which has just been enacted provides a general practitioner service for all wage earners whose income does not exceed £365 per annum in return for a weekly contribution shared equally by employer and employee. Provision has been made also for the voluntary inclusion of dependents of compulsory contributors. Thus over 80 per cent of the population is affected. No provision is made, however, for unemployed workers (about 5 per cent of the population) or for those small farmers and business men whose income is less than £365. Moreover, the health service provided is considered by many to be totally inadequate and to consist mainly of what the community in the past was best able to afford. Insurance makes available to contributors a general practitioner service, together with prescribed medicines, drugs and certain surgical appliances. Extra fees are payable for maternity services, major operations, laboratory tests and any specialist services. Thus the most efficient medical service still remains available to only a small section of the community.

From the point of view of the medical profession also national insurance as at present constituted is open to serious criticism. Members of the British Medical Association in Australia have clearly demonstrated that the capitation fee as originally proposed by the government is inadequate remuneration for the work it would entail. A royal commission has now been appointed by the government to investigate fully the financial aspect of the general practitioner's case. The only way in which a practitioner could maintain his present income, should the original proposals be put into operation, would be to build up a large panel. This however, has three disadvantages: he could do so only at the expense of his neighbor, at the expense of his health and at the expense of his own efficiency. The introduction of national health and pensions insurance in Australia therefore, although it will relieve the commonwealth government of a tremendous expenditure in pensions payments, has done little to provide a more efficient health service for the community as a whole.

Chemical Composition of Australian Foods

Until the present, those who wished to calculate the caloric equivalents, vitamin content or other quantitative aspect of diets in Australia have been restricted to figures published by American or English investigators. There have just been published, however, in the fifth report of the Commonwealth Advisory Council on Nutrition, the results of an extensive analysis of Australian foods for water, ash, protein, fat, carbohydrate and fiber content. As to calories, there are no very profound differences between Australian foods and foods overseas. The values for the protein of Australian breads (and of cereals generally) are shown to be lower than English and American figures, and meat also tends to have a low protein content in comparison. Dairy products show no appreciable differences, but the protein content of Australian vegetables and fruits is in most cases higher than that of other countries. On the basis of these analyses there has been drawn up an "economic index of foods," designed to function in times of national emergency, such as war or severe depression, which represents a compact summary of knowledge as to which foods contain the cheapest calories. Supplementary to this index is a list showing the amount of protein, fat and carbohydrate available for one penny in the case of some 214 foodstuffs. No account has been taken at this stage of mineral or vitamin content.

MINERAL IMBALANCE

In view of the fact that there exists in Queensland considerable evidence of a mineral imbalance in human beings, a series of analyses was carried out to determine the mineral content of some Queensland foods. The analytic results showed no especial deficiencies. While this allows attention to be paid to the question of supply and consumption, with an added sense of security, one physiologic aspect remains for consideration, and that is the question of variations in gross mineral requirements occasioned by altered habits or environments.

Immunity Reactions of Viruses

Dr. F. M. Burnet, whose contributions to the literature of filtrable viruses are both numerous and valuable, has carried out further research on the immunologic reactions of viruses and, in collaboration with E. V. Keogh and Dora Lush, working at the Walter and Eliza Hall Institute of Medical Research in Melbourne, has recently written a monograph on this subject. These workers consider that both plant and animal viruses can be most usefully considered as minute, organized, living microorganisms, at all events as far as the problems of immunity are concerned; and it is pointed out that, despite certain superficial differences due to the smaller size of the viruses, there is no real difference between the behavior of viruses and that of bacteria in their neutralization reactions with antisera. The study of neutralization reactions of the filtrable viruses has been difficult in the past, as titration of viruses in the living animal is at best inexact. Burnet has shown, however, that the chorio-allantoic membrane of the developing egg provides a means of virus titration of much greater accuracy than the animal, and he and his colleagues in Melbourne have made use of this method in the investigation of a number of animal viruses and their antisera.

Accumulation of data by the egg membrane technic has enabled these workers to attempt an analysis of virus neutralization reactions. They have shown that the viruses of vaccinia, influenza, louping ill, laryngotracheitis of fowls, Newcastle disease of fowls and rabbit myxomatosis conform in their reactions more or less closely to a hypothetical ideal case. This case was developed on the assumption that virus and antibody combined reversibly and that the infectivity or lack of it of a given virus particle was determined by the amount of antibody united to it at the time of effective contact with the susceptible cell. Each virus studied in detail showed some points of individuality, but all showed a general conformity with the broad outlines of the ideal case. On the basis of these data, Burnet and his co-workers have interpreted the neutralization reaction with animal-pathogenic viruses as follows: Virus inactivation by immune serum results primarily from union of antibody to the virus surface. This union is a reversible one; it takes place at a rate and reaches an equilibrium determined by the ordinary laws of reversible chemical unions. As a result of this union with antibody the virus is hindered from entering susceptible cells or from multiplying should it succeed in reaching that intracellular environment essential to its growth. Certain susceptible cells are protected against infection by lesser degrees of antibody coating on the virus particle than are required by other types of cell. It is shown also that the percentage law, discovered by Andrewes and Elford in the case of the bacteriophages, holds in the case of viruses as well, the reason for this being the relatively enormous amount of antibody to antigen in the neutralization reaction over a large range of antiserum dilutions.

Although this work has theoretical rather than directly practical significance, the monograph concludes with a consideration of the production of active immunity against virus infections. The use of living attenuated virus is held to be the method most likely to give success, the employment of killed virus being considered of little use for this purpose.

DESTRUCTION OF RABBITS WITH VIRUS

The idea that the virus or rabbit myxomatosis might be a possible means of controlling excessive increase in wild rabbit populations is of particular interest to Australia, and the Council for Scientific and Industrial Research is carrying out extensive experiments to ascertain the infectivity of the virus for Australian wild rabbits and to confirm its noninfectivity for other domestic and native wild animals. Although the virus of myxoma has been regarded as the most species specific of all viruses, it has been found that the chorio-allantois of the developing egg is susceptible to its infection, and Burnet's egg membrane technic has offered a single and inexpensive method of quantitative study of what would otherwise be a difficult and expensive investigation. An interesting preliminary epizootiologic observation in connection with rabbit myxomatosis is that the infected rabbit is shunned by his fellows. This will have an unfortunate effect in limiting the spread of the disease and will hinder the biologic control of the rabbit pest in Australia.

Poisoning from Benzene

A law was recently passed by which workers who are exposed to poisoning from benzene in the mirror industry have to report for periodic medical examination. Workers who handle or prepare varnishes which are made up with benzene or its derivatives have to report for medical examination after the first three months they are at work and at intervals of three months afterward. The examination will include counting of the erythrocytes and leukocytes. It is performed by a physician who is chosen by the manager of the industry. The intervals for medical examinations may be shortened if the physician believes it is necessary to do so. The results of the examination will be reported within two weeks to the physician appointed for the protection of workers in the given district. The latter can order discontinuation of work to persons showing symptoms of poisoning from benzene.

Prevention of Tetanus

Mr. Renaux, in a lecture before the Société belge de médecine et de chirurgie du travail, discussed serum prevention of tetanus, certain points of which are still a subject of controversy. The injection of antitetanic serum must be administered in cases of war wounds, wounds contaminated by either the soil or feces and those in which there is a great loss of tissues. However, there are certain cases with apparent exposure of the wounded to tetanus without development of the disease. It is a daily experience to see a benign evolution of wounds which were in danger of contamination by the tetanus bacilli. The development of tetanus in so large a number of cases is exceptional in spite of the fact that the number of cases in which antitetanic serum is administered is small. This experience shows that the body has natural defenses against tetanus bacilli as well as against other bacteria. It shows also that certain general conditions are necessary for the development of tetanus. These conditions are the association of bacteria, underfeeding and depression of the individual. There are also internal and external sources of contamination. An average of from 20 to 35 per cent of persons have tetanus bacilli in the intestine. Laceration of the perineum in the course of parturition is never complicated by tetanus, although in some cases the eventuality of the contamination may have existed. The speaker feels that tetanus does not necessarily develop from contamination of wounds. He said that when the administration of antitetanic serum is indicated it is advisable to desensitize the patient who possibly previously had been given serum.

Tropical Malaria in Hungary

In recent years tropical malaria has occurred in Hungary with fair frequency. Dr. Paul Végh, clinical assistant in Debrecen, made a special study of this disease, which in Hungary is most frequent from August to November. Last year he observed a good many cases in Debrecen. In the *Orvosi Hetilap* he says that in his cases the first attacks of fever came on after an incubation period of from four to six days. The feverish state is considerably longer than usual in tertian malaria, from thirty to thirty-six hours, and in ten to eighteen hours the pseudocritical fall of the fever can be observed. Then the maximum follows (febris tropica). In his cases the greatest difficulty in differential diagnosis was caused by abdominal typhus. All last year cases were sent to the clinic with the diagnosis abdominal typhus. The great prostration, eventually continuous fever and leukopenia remind one of typhus (the number of leukocytes in our cases was from 3,400 to 7,800). Nevertheless the characteristic monocytosis in the blood picture (from 8 to 19 per cent) should arouse suspicion of malaria, which has to be verified by microscopic examination. Treatment consisted in the administration of atabrine and plasmochin. Although the latter is fairly expensive, it has the advantage of destroying the gametes and in this way recurrences are brought to a minimum.

Resorcinol Poisoning in an Infant

A girl baby, 2½ months old, suffering from summer diarrhea, was given resorcinol 0.05 Gm. in 120 cc. of distilled water for five days. Her condition was aggravated so that her mother took her to the clinic. The patient on admission was very restless and languid. The pulse was 120 and weak. Her lips were cyanotic. The liver was very tender on pressure and even palpation. The spleen was enlarged and painful. The blood was chocolate colored. On treatment her condition made no change to the better. The blood picture showed anisocytosis, poikilocytosis and a few erythroblasts. Suspicion of poisoning arose and the bottle containing the medicine was sent for. It was found that the bottle contained a hundred times the amount of resorcinol prescribed; that is, instead of 0.05 Gm., 5 Gm. had been given. The baby took six teaspoonfuls of the medicine, 1.5 Gm. The baby was given a copious enema, a blood transfusion, oxygen inhalations and physiologic sodium chloride and dextrose solution. The baby recovered and was dismissed from the clinic on the twelfth day after admission.

Marriages

HOWARD W. GOURLIE, Thompsonville, Conn., to Miss Anne MacLeod of River Bennett, N. S., Canada, July 2.

ROBERT T. GRAY, Prospect, Ohio, to Miss Martha Sturgis Cohagen of Zanesville, June 6, at Columbus.

OSMYN WILLIAM MCFARLAND, Hebron, Neb., to Miss Rose Lolita Long of Baton Rouge, La., June 1.

RUDOLF WILLIAM HACK, Mokense, Ill., to Miss Willette Mary Drummond of Chicago in July.

PETER JOSEPH PARISI, Basin, Wyo., to Miss Kathryn A. Zietzke of Whitehall, Mont., July 31.

CAMILLE-AIME ROUSSIN to Miss Hortense Olivier, both of Joliette, Que., Canada, June 18.

IVAN WARD GESSLER, McMinnville, Tenn., to Miss Vera Field of Shaw, Miss., in June.

FRANK H. GREEN JR., Rushville, Ind., to Miss Jean Green at Belmont, Mass., July 1.

HARRY GREENBAUM to Miss Sylvia Frankel, both of Jackson, Mich., June 8.

Deaths

Dr. George E. de Schweinitz ☉ president of the American Medical Association in 1922-1923, died at his home in Philadelphia August 22.

Dr. de Schweinitz was born in Philadelphia Oct. 26, 1858, the son of Bishop Edmund Alexander de Schweinitz and Lydia de Schweinitz. He received his A.B. and A.M. degrees from Moravian College in 1876 and his M.D. from the University

GEORGE E. DE SCHWEINITZ, M.D.
1858-1938

of Pennsylvania in 1881. After an internship in the Children's Hospital and in the University of Pennsylvania Hospital he served as professor of anatomy for Dr. Joseph Leidy at the University of Pennsylvania from 1883 to 1886. He also taught therapeutics in the Medical Institute of Philadelphia from 1882 to 1887. He then turned his attention to ophthalmology and became lecturer on medical ophthalmoscopy in the University of Pennsylvania in 1891-1892 and professor of ophthalmology in the Philadelphia Polyclinic and College for Graduates in Medicine, 1891-1893. He was clinical professor of

ophthalmology at Jefferson Medical College, 1892-1896, and professor of ophthalmology, 1896-1902. In 1902 he became professor of ophthalmology at the University of Pennsylvania, holding this position until 1924, and then professor of ophthalmology at the Graduate School of Medicine of the University of Pennsylvania from 1924 to 1929. In 1929 he was made professor emeritus of ophthalmology. During the same period he served as consulting ophthalmologist to most of the leading Philadelphia hospitals.

Early in his career he became closely identified with the work of the profession in many different medical societies, including the Philadelphia County, Pennsylvania state and American Medical associations, the Philadelphia Pathological and Neurological societies, the American Academy of Ophthalmology and Otolaryngology and the American College of Surgeons. He was secretary of the Section on Ophthalmology of the American Medical Association in 1891-1892, and chairman, 1896-1897. He served as president of the College of Physicians of Philadelphia, 1910-1913, and of the American Ophthalmological Society, 1916. He was elected an honorary member of the Ophthalmological Society of the United Kingdom and gave the Bowman lecture in 1923. He was also a member of the French, British and Belgian ophthalmologic societies and of all international congresses. As a citizen he was prominent in many affairs, holding memberships on the boards of institutions for the blind and also of the National Institute of Social Sciences and similar groups. In 1924 he was elected a trustee of the University of Pennsylvania and was appointed chairman of its Board of Medical Affairs in 1928.

During the World War he was appointed to the Council of National Defense in 1917 and commissioned a major on April 9, 1917, being advanced to lieutenant colonel in May 1918. He was ordered to duty in the Surgeon-General's office in September 1917 and went overseas in October, remaining until March 1918. He was then returned to the Surgeon-General's office as officer in charge of ophthalmology and established the School of Ophthalmology in the Medical Officers' Training Camp at Fort Oglethorpe. At the end of the war he was appointed consultant in ophthalmology and made a member of the editorial board of the medical history of the war. In April 1919 he was commissioned colonel and in 1922 brigadier general in the Medical Reserve Corps.

Dr. de Schweinitz was widely known for his contributions to the science of ophthalmology, having devoted his research par-

ticularly to toxic amblyopias, the relation of auto-intoxication to ocular disorders, pathologic changes of various ocular diseases, relation of cerebral decompression to the cure of choked disk, ocular angiosclerosis, pathogenesis of choked disk, relation of focal infection to ocular diseases, blindness in Guernsey calves, comparative ophthalmology, ophthalmic surgery and pulsating exophthalmos. For this investigative work he achieved wide recognition. He was awarded the Leslie Dana Gold Medal in 1930 by the National Society for the Prevention of Blindness in cooperation with the St. Louis Society for the Blind. For this award he received the personal congratulations of President Herbert Hoover. He had also been called to attend Woodrow Wilson when he was President of the United States. The Howe prize medal in ophthalmology in 1927, the Huguenot Cross in 1928, the bronze plaque of the French Society for Ophthalmology in 1923, and the Alvarenga prize in 1894 were other honors to Dr. de Schweinitz.

The literary contributions of Dr. de Schweinitz included chiefly his textbook on "Diseases of the Eye," which has passed through numerous editions. Moreover, he participated in the editing and publication of seven additional textbooks in his field, and his original papers numbered hundreds.

Dr. de Schweinitz was conspicuous as a recognized leader in every activity in which he took part. He spoke with poetic and polished diction, always in behalf of the highest ideals of medical science. His manner was kindly and his presence was the personification of the dignity coupled with sincerity and humanity which are the characteristics of the truly great physician. His graciousness and nobility have been for many years a tradition among physicians.

John Martin Wheeler ☉ New York, professor of ophthalmology at the Columbia University College of Physicians and Surgeons, New York, died, August 22, at his summer home in Underhill Center, near Burlington, Vt., aged 58. Dr. Wheeler was born at Burlington, Vt., Nov. 10, 1879. He graduated from the University of Vermont in 1902, received the medical degree in 1905 and the master of science the following year. In 1928 Dr. Wheeler was appointed professor of ophthalmology at Columbia University and in 1931 director of the Institute of Ophthalmology of the Columbia-Presbyterian Medical Center. He was a member and past president of the American Academy of Ophthalmology and Oto-Laryngology, past president of the Society of Plastic and Reconstructive Surgery, a member of the American Ophthalmological Society and a fellow of the American College of Surgeons. Dr. Wheeler was consulting ophthalmologist to the Presbyterian, Fifth Avenue and Bellevue hospitals, Neurological Institute, Sloane Hospital for Women, and New York Eye and Ear Infirmary, New York, St. Luke's Hospital, Newburgh, N. Y., and Hackensack (N. J.) Hospital. He served during the World War as a captain and later as a major. In 1936 he was presented with the Leslie Dana Gold Medal for "outstanding achievements in the prevention of blindness and the conservation of vision" by the National Society for the Prevention of Blindness in cooperation with the St. Louis Society for the Blind. He was formerly a member of the board of directors of the National Society for the Prevention of Blindness. He was awarded the honorary degree of doctor of science by the University of Vermont in 1928 and by Middlebury (Vt.) College in 1933. Dr. Wheeler was also a member of the board of trustees of the University of Vermont. He achieved world wide fame as ophthalmic surgeon in many cases affecting notable people. His research was chiefly in the field of surgical technic applied to the eye and related structures.

JOHN M. WHEELER, M.D.
1879-1938

Howard Moore Williamson * Lieut. Col., M. C., U. S. Army, Manila, P. I.; Washington University School of Medicine, St. Louis, 1915; fellow of the American College of Surgeons; served during the World War; entered the medical corps of the regular army as a first lieutenant in 1920, passing through the various grades to lieutenant colonel in April, 1938; aged 47; died, June 2, in the Sternberg General Hospital.

McLeod Gillies, Charleston, W. Va.; University of Manitoba Faculty of Medicine, Winnipeg, Manit., Canada, 1924; served during the World War; member of the West Virginia State Medical Association; on the staffs of the Mountain State, Kanawha Valley, St. Francis, McMillan and Staats hospitals; aged 45; died, June 21, in Baldur, Manit., of spontaneous pneumothorax of the right lung.

Walter Karl Seelye, Seattle; State University of Iowa College of Medicine, Iowa City, 1892; member of the Washington State Medical Association, American Academy of Ophthalmology and Oto-Laryngology and the Pacific Coast Oto-Ophthalmological Society; fellow of the American College of Surgeons; aged 70; died, June 24, of arteriosclerosis and myocarditis.

William Edward Zilisch * Wausau, Wis.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; past president of the Marathon County Medical Society; on the staffs of the Wausau Memorial Hospital and St. Mary's Hospital; aged 64; died, May 1, of Parkinson's disease.

Charles Garrard Daugherty, Paris, Ky.; University and Bellevue Hospital Medical College, New York, 1899; member of the Kentucky State Medical Association; past president of the Bourbon County Medical Society; aged 66; on the staffs of the Massie Memorial Hospital, where he died, June 8, of hypertensive heart disease.

George Foster Gourley, Steubenville, Ohio; Ohio Medical University, Columbus, 1903; member of the Ohio State Medical Association and the American Academy of Ophthalmology and Oto-Laryngology; on the staffs of the Gill Memorial Hospital and the Ohio Valley Hospital; aged 59; died, June 28, of coronary thrombosis.

Everett Nathaniel Bennett, Kokomo, Ind.; Western Reserve University School of Medicine, Cleveland, 1915; member of the Indiana State Medical Association; on the staffs of St. Joseph and Good Samaritan hospitals; served during the World War; aged 52; died, June 2, of chronic valvular heart disease.

George Joseph Youell, Philadelphia; Medico-Chirurgical College of Philadelphia, 1904; during the World War was chief medical examiner for a draft board; on the staffs of the Northeastern and St. Mary's hospitals; aged 55; died, May 30, in the Fitzgerald-Mercy Hospital, Darby, Pa., of cerebral hemorrhage.

George Oscar Switzer, Ludington, Mich.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1881; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1897; member of the Michigan State Medical Society; aged 84; died, June 15, in the Paulina Stearns Hospital.

John Robert Wilson * Bennington, Vt.; Columbia University College of Physicians and Surgeons, New York, 1905; member of the American Academy of Ophthalmology and Oto-Laryngology; aged 58; on the staff of the Putnam Memorial Hospital, where he died, June 28, of acute myocarditis and nephritis.

John Nivison Force, Berkeley, Calif.; University of California Medical Department, San Francisco, 1901; chairman of the department of hygiene, University of California, and for many years professor of epidemiology; aged 60; died, June 21, in a hospital at San Francisco of carcinoma of the stomach.

Jesse Howard Robbins, Sioux City, Iowa; Sioux City College of Medicine, Sioux City, Iowa, 1895; member of the Iowa State Medical Society; formerly county coroner; on the staff of St. Vincent's Hospital; aged 67; died, June 18, of coronary thrombosis and arteriosclerosis.

James William Thomas, Cross Plains, Tenn.; University of Louisville (Ky.) Medical Department, 1910; member of the Tennessee State Medical Association; aged 60; died, June 21, in a hospital at Nashville of cerebral embolism and pulmonary embolus, following a cholecystectomy.

John Preston, Austin, Texas; University of Virginia Department of Medicine, Charlottesville, 1872; Bellevue Hospital Medical College, New York, 1873; formerly superintendent of the State Lunatic Asylum; aged 86; died, June 27, of acute cystitis and septicemia.

Gilce Dick Moore Lambdin, Electra, Texas; Kansas City Medical College, 1905; member of the State Medical Association of Texas; served during the World War; formerly health officer of Chautauqua County, Kan.; aged 54; died, June 25, of lymphosarcoma.

Chase Adam Shafer, Chester, W. Va.; Chicago College of Medicine and Surgery, 1917; past president of the Hancock County Medical Society; on the staff of the East Liverpool (Ohio) Hospital; aged 50; died, June 26, of carcinoma of the colon.

Robert Colwell Hefebower, Cincinnati; Miami Medical College, Cincinnati, 1889; fellow of the American College of Surgeons; aged 72; died, June 3, in the Good Samaritan Hospital of cerebral hemorrhage, following carcinoma of the prostate.

Lewis Henry Hector * Long Beach, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; member of the Medical Society of the State of Pennsylvania; aged 59; died, June 24, of carcinoma of the cecum.

Thomas Sidney Whitelock Sr. * San Diego, Calif.; Gross Medical College, Denver, 1899; aged 75; on the staffs of the Mercy Hospital and of the Scripps Memorial Hospital, where he died, May 25, of coronary occlusion.

William Cobb Whitfield, Salisbury, N. C.; University of Maryland School of Medicine, Baltimore, 1884; member of the Medical Society of the State of North Carolina; aged 77; died, May 13, of cerebral hemorrhage.

George L. Roark, Tabor, Iowa; Northwestern University Medical School, Chicago, 1918; member of the Iowa State Medical Society; aged 57; died, June 11, of chronic valvular disease and angina pectoris.

James Glover Tompkins, Edgefield, S. C.; University of the City of New York Medical Department, 1883; past president of the Edgefield County Medical Society; aged 85; died, June 12, of senility.

John Alfred Gillean, Dallas, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1885; aged 78; died, June 8, of coronary thrombosis, prostatic hyperplasia and arteriosclerosis.

Arlington Walton Diven, Martins Ferry, Ohio; University of the South Medical Department, Sewanee, Tenn., 1895; formerly county coroner; aged 66; died, June 4, of bronchopneumonia.

William H. Fuller, Friendship, Ind.; Cincinnati College of Medicine and Surgery, 1895; aged 66; died, June 6, in a hospital at Milan, of injuries received in an automobile accident.

Edward Russell Hanlon, Los Angeles; Cooper Medical College, San Francisco, 1899; member of the California Medical Association; aged 61; died, June 24, of chronic myocarditis.

Lawrence Edward Gausepohl, St. Louis; St. Louis College of Physicians and Surgeons, 1914; aged 50; died, July 5, of edema of the brain, chronic nephritis and chronic myocarditis.

Ira Albertum Tripp, Cleveland; Trinity Medical College, Toronto, Ont., Canada, 1895; aged 67; died, May 30, in a local hospital of pulmonary embolism and bronchopneumonia.

John Walton Smith, Payette, Idaho; University of Tennessee Medical Department, Nashville, 1894; member of the Idaho State Medical Association; aged 85; died, May 19.

James M. Hamilton, Oakmont, Pa.; Jefferson Medical College of Philadelphia, 1876; member of the Medical Society of the State of Pennsylvania; aged 88; died, May 20.

Edwardina M. Grant, Cleveland; Cleveland Homeopathic Medical College, 1902; aged 74; died, June 3, of carcinoma of the colon, arteriosclerosis and carcinomatosis.

Everett Field Darling, New York; Columbia University College of Physicians and Surgeons, New York, 1900; aged 63; died, May 9, in St. Luke's Hospital.

B. C. Maud Speer, Tamaqua, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1892; aged 73; died, May 24, in the Pottsville (Pa.) Hospital.

Bonnard Teegarden * New York; Eclectic Medical College, Cincinnati, 1926; aged 35; died, June 28, in Tucson, Ariz., of coronary occlusion.

Adelard Odilon Falardeau, Fournier, Ont., Canada; McGill University Faculty of Medicine, Montreal, Que., 1921; aged 51; died, June 7.

D. Roy Hunt, Ellisville, Miss.; Memphis (Tenn.) Hospital Medical College, 1904; aged 68; died, in May.

John G. McClellan, Bristol, Tenn.; Eclectic Medical Institute, Cincinnati, 1889; aged 75; died, May 20.

Correspondence

PHYSIOLOGIC ACTION OF HYPOGLYCEMIA AND METRAZOL ON NERVOUS SYSTEM

To the Editor:—The investigations reported in *THE JOURNAL*, April 30, to which Favill refers in the issue of July 30, were on the physiologic action of hypoglycemia and metrazol on the central nervous system. They, together with a critical analysis of the physiologic mechanism involved in other therapeutic procedures successfully used in schizophrenia, led me to the theory that these procedures, introduced by the inventors for entirely different reasons, act by stimulating the sympathetic centers directly or indirectly. Clinical observations of Singer, the work of Hoskins and his collaborators, and that of others cited in the final paper (Gellhorn, Ernst: Effects of Hypoglycemia and Anoxia on the Central Nervous System, *Arch. Neurol. & Psychiat.* 40:125 [July] 1938) support the conclusion that the sympathetic nervous system is deficient in these patients. The observations of Petersen that an aggravation in schizophrenic symptoms is accompanied by a fall of blood pressure is in line with the argument, although Petersen admits that similar changes of blood pressure frequently occur in normal persons. Moreover, the fall of blood pressure as such may be due to many different causes and is certainly not specific for a diminution in sympathetic tone.

The mechanism by which insulin evokes a sympathetic response is well established and referred to in any textbook of physiology.

I have not added a "new" proof that schizophrenic patients have a disturbance in the sympathetic centers. But the elucidation of the essential physiologic mechanisms by which the procedures commonly used in the treatment of this disease act created a new basis for therapeutic studies of this disease through animal experimentation, although the disease itself is not reproducible in them.

I believe with Cannon (*The Pharos of Alpha Omega Alpha* 1, No. 2, 1938) "that value may follow from a polemic if the discussion is kept on a factual level."

ERNST GELLHORN, M.D., PH.D., Chicago.

BLOOD PRESERVATION TECHNIC

To the Editor:—In *THE JOURNAL*, July 23, appeared an article by Bernard Fantus describing the blood preservation technic used in the Cook County Hospital. I was surprised to see that with the technic described in this article the patient does not receive pure blood but blood diluted in equal parts with sodium chloride solution. When a blood transfusion is indicated, the patient ought to get the benefit of all the vital constituents of the blood in the physiologic concentration and not a highly diluted mixture. Such dilution is entirely unnecessary if one adheres to the original technic which I described nearly twenty-four years ago (*A New and Greatly Simplified Method of Blood Transfusion*, *M. Rec.* 87:141 [Jan. 23] 1915).

I have repeatedly pointed out that unless the cannula is of proper size and is inserted properly into the vein, guaranteeing a rapid flow of the blood from the donor's vein into the glass receptacle, early stages of clotting will occur. When these few technical points are observed, dilution of the blood is absolutely unnecessary.

It is interesting to note that over twenty years ago the late Dr. Brem carried citrated blood to places seventy miles away from Los Angeles, the first practical application of the "stored blood" method. The storage of the blood originated in Russia. I think the Cook County Hospital was among the first institutions to popularize the method in this country.

While it is too early yet to pass definite judgment on the merits of the "stored blood" method, it would be unfortunate if the impression should be created that a dilution of the blood with equal parts of a sodium chloride solution was essential for the successful storage of blood. I am sure that many clinicians would object to using blood in this diluted form.

It is possible that storage of citrated blood may become very popular and be used extensively. For this reason it seemed of importance to point out that undiluted blood may be stored effectively.

Before closing I would like to suggest that the term "blood bank" which has been used for the storage of citrated blood be discarded. "Banks" are not only places of deposit but they are run for financial gain. As blood is stored in order to facilitate the technic and not for financial gain, "blood storage" or a similar term would be preferable.

RICHARD LEWISOHN, M.D., New York.

"DEFICIENCY OF VITAMIN B AND PEDICULOSIS"

To the Editor:—In *THE JOURNAL* July 16, page 257, is an editorial on "Deficiency of Vitamin B and Pediculosis." The author suggests that the corroboration of this fact would be helpful. I am interested in this remark, for on June 14, 1933, I read an article before the American Medical Association in Milwaukee: "Ocular Disturbances Produced in Experimental Animals by Dietary Changes." In this article I wrote: "At the end of ten weeks, animals on this diet were unable to care for their fur and their bodies were literally covered with lice."

ARTHUR M. YUDKIN, M.D., New Haven, Conn.

MEDICAL PORTRAITS ON STAMPS

To the Editor:—I was interested in the editorial in *THE JOURNAL* August 6 relative to medical portraits on stamps. I think too that we should have stamps for doctors of the United States. I am a collector of stamps relating to medicine. There has been one doctor in the United States that has been honored on a stamp, not so much because he was a good doctor but because he was a good diplomat and lawyer. Manasseh Cutler appeared on the Northwest Territory Stamp of this year. This will be found in "American History as Told by Postage Stamps," by Charles C. Gill, M.D., of Denver, and published by the *Weekly Philatelic Gossip* of Holton, Kan., page 28.

EVON WALKER, M.D., Ottumwa, Iowa.

EDITORIAL NOTE.—Manasseh Cutler was born in Killingly, Conn., in 1742, and graduated at Yale in 1765, according to the *Encyclopedia Britannica*. After being a school teacher and a merchant, and occasionally appearing in the courts as a lawyer, he decided to enter the ministry. From 1771 he was pastor of the Congregational church at what now is Hamilton, Mass. In the American Revolution he served as chaplain, thereafter supplementing his ministry by the practice of medicine and the conduct of a private boarding school. In 1786 he became interested in the settlement of Western lands, and in the following year, as agent of the Ohio Company, which he had taken a prominent part in organizing, he made a contract with Congress whereby his associates, former soldiers in the Revolutionary War and business men, might purchase 1,500,000 acres of land in the region north of the Ohio at the mouth of the Muskingum river. He also took a leading part in drafting the famous Ordinance of 1787 for the government of the Northwest Territory. From 1801 to 1805 he was a Federalist representative in Congress. A versatile man, Cutler conducted painstaking astronomical and meteorological investigations and made researches of scientific value in botany. He died in Hamilton, Mass., July 28, 1823.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

DAY BLINDNESS OR NIGHT BLINDNESS

To the Editor:—In the article "The Pharmacology and Therapeutics of Vitamin A," by Dr. S. W. Clausen, it is said that night blindness "occurs in various diseases of the eye such as toxic amblyopia, retinitis pigmentosa and detachment of the retina." I have been taught that toxic amblyopia is a case of day blindness and not of night blindness. Who is right?

M.D., New York.

ANSWER.—Duke-Elder defines night blindness as the condition in which vision in moderate illumination is good but in feeble illumination is deficient. Day blindness is a symptom showing characteristics opposite to night blindness, the patient seeing poorly in good illumination and normally in the dusk. Central vision is a function of the fovea, which part of the retina has poor powers of dark adaptation. Consequently, disease (or congenital conditions) reducing the effectiveness of the peripheral portions of the retina throws the entire weight of vision on the fovea and there results the condition known as night blindness. On the other hand, in conditions in which the fovea does not function properly, as in toxic amblyopia, central vision, which is best under good illumination, is reduced and the burden of vision is thrown on the peripheral retina, which at best has a low visual acuity.

PHYSICAL THERAPY FOR DEEP TISSUES AND ARTHRITIS

To the Editor:—Which is preferable for the late treatment of injuries to the bones, muscles and ligaments—infra-red or short wave diathermy? In the use of the latter, is there any evidence to show deleterious consequence to delicate tissues, such as the eye or brain, in treating, for example, the sinuses? Which is preferable for the treatment of the pain from arthritis? It seems impossible to get anything but a "Scotch verdict" from the textbooks, and I am suspicious of the claims made by the manufacturers.

CLEMENT H. ARNOLD, M.D., Palo Alto, Calif.

ANSWER.—Any answers to these questions must be of a qualifying nature owing to the great multitude of factors influencing the end results of treatment. Such factors include (1) the individual reaction (idiosyncrasies of the patient), (2) the area to be treated and (3) the dosage.

While all three of these must be considered, it is the third which offers the chief difficulty in physical therapy. The dose depends almost entirely on the method of administration; different technicians differ both in technic and in judgment. X-ray therapy, in which the dosage can be quite accurately controlled, is a striking exception. In short wave diathermy, for example, the dose and the result will in part depend on the amount of current used, the size of and the distance between the electrodes and the spacing between the electrodes; i. e., the distance from the skin and, of course, the time or duration of the treatment. In the case of infra-red radiation, the dosage would depend in part on the power of the lamp, the distance from the lamp to the skin, the anatomic structure and depth of the part treated, and the duration.

In the treatment of bones, muscles and ligaments, the choice between infra-red radiation or short wave diathermy should perhaps be made on the accessibility of the part to be treated. In case the injury is comparatively superficial, infra-red may well be chosen. It is perhaps more economical, easier to manipulate, and above all easier to control and thus less dangerous. Furthermore, the part treated is more easily inspected and may, if desired, be subjected to brief intermittent massage applications during the administration of heat. The effectiveness of the treatment may also be varied by the application of counterirritants, or by wet compresses. The latter may be kept on continuously during the treatment if moist heat is desired. The compress is kept hot by the lamp, and more water is periodically poured on the cloth to replace that which evaporates. This is an effective method, for example, of keeping a continuous hot boric acid compress on open wounds.

A second and equally important, if not more important, question is How much heat should be introduced? Little or no work has been done on this all important problem. The tendency among those interested in physical therapy seems to be to concentrate on means to create higher temperatures and

then to evaluate the efficiency of an apparatus on this basis. This is to be regretted, since there appears to be no information available which indicates that it is better to treat a sprained ankle by a temperature of 106 F. than, for example, 102 or 103.

The matter of dosage (temperature and time) is also an open question. The present tendency is, it appears, to treat to the patients' tolerance, but no data which tend to support the theory that such intense doses are more desirable than some lesser ones are available.

There should be no deleterious consequences to delicate tissue, such as the eye or brain, in treating, for example, sinuses by short wave diathermy, provided the dose is kept within safe limits.

There appears to be no generally accepted physical treatment for the pain of arthritis. This is due, no doubt, to the many forms of arthritis and the difficulty of correct diagnosis.

While at present the effects of short wave diathermy are attributed solely to the heat produced, there are present, no doubt, other secondary effects from the current—effects which have not as yet been segregated satisfactorily but which, if once isolated, may prove of therapeutic significance.

HAIRY BLACK TONGUE

To the Editor:—A man about 30 years of age has hairy black tongue. The case is typical and microscopic study presents numerous broken streptothrix filaments in the field. The condition is of about seven weeks' standing and is gradually becoming worse. The Wassermann reaction is negative. Oral hygiene has been carried out as well as abstinence from tobacco and also hot and acid foods. I have searched as much literature as I have at my disposal and can find no definite treatment for this condition. I would appreciate any suggestions in the way of therapy and prognosis.

CHARLES F. ENGELKING, M.D., Dalton, Ga.

ANSWER.—Hairy black tongue (nigrities, hyperkeratosis) is a hypertrophy of the filiform papillae of all or a portion of the medial dorsum. It usually comes on insidiously and without demonstrable cause, is asymptomatic and unimportant clinically, may remain for weeks or years, and is resistant to treatment. The failure of normal exfoliation of cellular scales results in the harboring of great numbers of bacteria in the abnormal papillary tufts. These bacteria may be staphylococci, streptococci, yeast, spore formers or Leptothrix, but when a *Penicillium* such as *Mucor niger* is present the color may be black. It is believed that this is coincidental to the coating.

Other causes of the hyperkeratosis include the use of oxidizing agents (such as sodium perborate), the presence of a hyperacidity or of a gastritis with or without hyperacidity (including neoplasm), irritating mouth washes or fever. Other possible causes of the dark coloration include silver nitrate, tannic acid, ferric chloride in the presence of blood, and dark coloring matter in medication or food.

There is no relationship between black tongue of man and that of dogs (which is caused by a vitamin deficiency).

The literature suggests the use of scrapers and salicylates to rid the tongue of the excess tissue but indicates that this is not remarkably effective.

Since the present case is not responsive to hygienic measures and is apparently complicated by the presence of a streptothrix, it is suggested that local applications of thymol or its isomer carvacrol be used. Thymol is effective against molds, is only slightly soluble in water, and is highly effective as a mouth wash in saturated solution (1:1,000).

COLD AND HOT COMPRESSES IN CELLULITIS

To the Editor:—What is the rationale of cold compresses of magnesium sulfate in cellulitis? ROBERT A. ROBINSON, D.D.S., Albany, N. Y.

ANSWER.—Hot wet dressings produce an edema of the underlying tissues and capillary changes in the vessels with a varying amount of cellular infiltration. This may either hasten resolution or aid localization of the infection. Wet dressings are contraindicated when the tissues will not permit increased swelling without danger of spreading the infection and producing deeper involvement of tissues, cavities or fascial spaces. Under these conditions, before drainage is indicated cold compresses are desirable since they tend to lessen the congestion and also tend to relieve the pain. It is not desirable to apply constant ice cold compresses owing to danger of ischemia with lowered resistance of the tissues and also because relief of pain may delay necessary drainage.

There is often relief of pain by the cold produced by the evaporation of solutions if the dressings are not too thick. For

this purpose a 60 per cent alcohol solution or equal parts of boric acid solution and alcohol may be applied at frequent intervals.

A 25 per cent solution of magnesium sulfate probably has no advantage over boric acid solution or water, although it has an anesthetic action, but like lotion of lead and opium it is not absorbed to any appreciable extent through the unbroken skin. After incision of a suppurating area the use of a 25 per cent solution of magnesium sulfate favors relief of pain, a decrease of swelling and the separation of the necrotic tissue.

The protective and splinting action of dressings and the soothing reaction which follows the application of a cool or easily evaporating solution is often credited to the analgesic effect of some popular lotion. In acute inflammation, where increased swelling will not tend to spread the infection, and in the chronic or subacute forms hot wet dressings are usually indicated.

CUPPING OF NAILS IN INFANT

To the Editor:—I have under observation a boy baby aged 9 months. He is apparently normal in every way except for a slight cupping of his finger nails. There is a slight concavity on the exposed surface of the nails, especially pronounced on the index and middle fingers of both hands. The toe nails are slightly concave also. This nail change has become apparent only in the last two months. When the child was 3 months old he had a temperature of the type seen in tertiary malaria, reaching as high as 103.5 F. with a leukopenia of 4,000. Hemoglobin was 70 per cent. No plasmodia of malaria were found. The baby was placed on quinine sulfate and tincture of ferric chloride and within one week he was fever free. He has shown a normal weight gain throughout his life. His diet consists of pasteurized milk, Karo, egg yolk, pabulum, vegetables and cod liver oil. What dietary change might be made and what mineral or vitamin therapy would be indicated? There is no dermatologist in this vicinity.

M.D., Illinois.

ANSWER:—The condition described is suggestive of several conditions affecting the nails. The first possibility is a rare condition of unknown etiology known as koilonychia, or spoon nails. This is a progressive condition usually beginning in one or more fingers and extending into the others. The other possibility which must be considered is that of a postinfectious dystrophy of the nails, or onychatrophy. This condition infrequently follows a severe systemic infection or infectious disease and may be characterized by crumbling, spotting or fragility of the nails. The lapse of four months before the appearance of the cupping does not rule this out as the etiologic factor. The child apparently had a systemic disease probably grippal in character.

The treatment of this condition consists in building up the general health of the child. No mention was made of vitamin C in the diet described and if this has not been administered it should be started at once in the form of orange or tomato juice. An iron tonic should be added.

Other cereals, vegetables and liver soup, mashed ripe banana, apple sauce and baked potato should also be added gradually to the diet at this age.

The local treatment of this condition is unsatisfactory. If there is no fragility or crumbling of the nail substance, nothing needs to be done. If there should be splitting or breaking, the hands should be protected by stocking or celluloid cuffs.

TELANGIECTASIA AND NASAL HEMORRHAGES

To the Editor:—A man, aged 63, has hereditary familial telangiectasia. He has had profuse hemorrhages from the nose since the age of 20. The nasal mucous membrane shows milium telangiectatic spots as well as extensive ulcerations extending into the depths of the nose. In the past he has tried methods of increasing the coagulability of the blood such as thromboplastin, alum and snake venom. He has also used local measures, such as ice and nasal pressure. Small transfusions of from 200 to 300 cc. have erased the bleeding for several days. In spite of all these measures he still bleeds profusely and has an anemia with a hemoglobin of approximately 45 per cent. I would appreciate any help that you will offer.

BERNARD SELIGMAN, M.D., Brooklyn.

ANSWER:—As a rule, telangiectasia affects the vessels of the nasal septum in its cartilaginous portion and in the vast majority of cases these vessels can be destroyed by the galvanocautery. In elderly persons hypertension may be the predisposing cause of recurring hemorrhages from the septum, middle turbinate and even the antrum.

Since the usual local measures have failed and, in addition, various constitutional agents have been given without avail, it would be advisable to try radium, which may cause sufficient fibrosis to contract the offending vessels or even cause them to disappear. A capsule containing 25 mg. of radium element sheathed in thin rubber tubing is inserted into each nasal cavity at about the level of the lower border of the middle turbinate,

being kept in place by gauze packing below as well as above. The radium is left in place for four hours, making a total of 200 mg. hours administered. This dose may be repeated within two weeks without danger. The ulcers will undoubtedly heal but one will have to expect a certain amount of atrophy to take place as a result of the irradiation. It will be necessary, therefore, to keep the nasal cavities well lubricated with petrolatum or liquid petrolatum for an indefinite period. The patient should also be warned of the possibility of anosmia resulting from the atrophic changes in the mucous membrane.

HYPNOTICS

To the Editor:—Please discuss the use of hypnotic drugs not belonging to the barbituric acid or bromide groups to which there is frequent objection. What drugs would you advise for topical application to the sigmoid or rectum in ulcerated colitis?

M.D., Washington.

ANSWER:—There is probably no hypnotic that is entirely without disadvantage, but one of the least objectionable is carbromal (a 0.3 Gm. tablet at bedtime), which is essentially not a bromide. It may give rise to acne in persons highly susceptible to bromide. Chloral hydrate is an old reliable remedy; in a dose of 1 Gm. taken freely diluted in milk, it will compel sleep; like all other powerful hypnotics, it is habit producing and therefore should be prescribed with the necessary precaution against habituation. One such measure is to prescribe the chloral in syrup of glycyrrhiza (1 Gm. to 5 cc.) in a 100 cc. bottle, to have the patient add a teaspoonful of water for each teaspoonful of medicine he has taken. It is also well to have the patient take a dose only on those nights when he is unable to sleep and has not slept well for a night or two before. The use of all such hypnotics must be accompanied by treatment directed against the cause of the insomnia.

The kind of topical application to be used in ulcerative colitis depends on the acuteness of the condition. Only soothing applications are tolerated in the acute form and among these might be mentioned bismuth subgallate, 1 tablespoonful to 500 cc. of starch water, to be retained as long as possible and given once daily after a cleansing enema.

PROBABLE MENINGOVASCULAR SYPHILIS

To the Editor:—A Negro aged 27, whom I had the opportunity of seeing only once, had recurrent headaches for the past three months, increasingly severe, the attacks beginning in the right frontal region and spreading across the forehead, over the entire head and down the back of the neck. There is no nausea or vomiting. There have been transitory diplopia, attacks of vertigo with syncope, periodic swelling of both orbital regions, usually greater on the right, and two or three attacks of partial blindness in the right eye, no visual defects having been noted in the left eye. He has had no edema of other parts of the body or face. His past history is negative for syphilis, but a Wassermann test of the blood, taken a few weeks ago on account of persistent headache, was 4 plus. The patient has refused lumbar puncture. Urinalysis has not been done. The pulse rate is 50 and the blood pressure 150 systolic, 100 diastolic. The pulse is strong and full. The patient is in great pain but well oriented. His speech is normal. His neck is slightly stiff. The right pupil is fixed in mid-dilatation and is regular. There is a small retinal hemorrhage lateral to the disk but no papilledema. The left pupil was regular and reacted briskly to light; the left fundus was not observed satisfactorily. There was no evidence of other cranial nerve injury. Vision was not tested. General physical examination was negative. The most probable diagnosis here, I think, is acute meningovascular syphilis. But in the presence of symptoms predominant on the right side and of unilateral (right eye) abnormalities should not intracranial neoplasm also be suspected? How often does a unilateral Argyll Robertson pupil occur?

M.D., Oklahoma.

ANSWER:—The unilateral fixed and partially dilated pupil conforms to that seen in meningovascular syphilis. The pupil as described is not an Argyll Robertson pupil. The Argyll Robertson pupil in its narrow sense is a contracted pupil. The Argyll Robertson pupil is at times unilateral. The syphilitic pupil, corresponding to the one described, is frequently unilateral. This is referable to a lesion of the third cranial nerve. The transient attacks of diplopia may have the same basis.

In the case cited the observations given warrant the diagnosis of meningovascular syphilis. The examination of the spinal fluid would, however, be necessary to confirm the diagnosis. In the event that the spinal fluid showed no evidences of syphilis, the diagnosis of an expanding intracranial lesion would be favored. It is evident that the short duration and the progressive nature of the symptoms indicate an acute process. The spinal fluid should be strongly positive if the diagnosis of syphilis is correct. In face of the patient's refusal to have a spinal puncture, the therapeutic test with anti-syphilitic treatment may be substituted and should give rapid improvement if the diagnosis is correct.

NEUROSYPHILIS AND DERMATITIS FROM ARSENICALS

To the Editor:—A woman aged 29 complained of ataxia and dizziness in July 1937. She had a vertical and lateral nystagmus, sluggishly reacting pupils, hyperactive tendon reflexes and a slight Romberg sign. The Wassermann reaction was strongly positive. She was unaware of her infection and I could not determine the date of onset. A dose of 0.25 Gm. of neoarsphenamine intravenously produced an extensive exfoliative dermatitis which took about three weeks to improve with local treatment and sodium thiosulfate. There was also considerable temporary loss of hair from the scalp. She was then put on 0.2 Gm. of thiobismol in 2 cc. of water intramuscularly twice weekly. She also received iodides to tolerance. She has had forty treatments to date and is greatly improved, but the Wassermann reaction is unchanged. Her mouth is almost endentulous and she wears dentures, but there is a tendency to stomatitis if treatment is pushed. I have not examined her spinal fluid yet, as it is probably positive and I can make little change in treatment anyway. I do not feel that I am warranted to try the arsenicals again. Could you suggest further treatment? Should I try mercury, mapharsen, tryparsamide, sulfarsphenamine or acetarsone? Are the oily bismuth preparations superior to the water-soluble ones?

M.D., Oregon.

ANSWER.—This patient cannot be treated intelligently without examination of the spinal fluid and without accurate neurologic and psychiatric definition of the type of neurosyphilis from which she suffers. The information given is inadequate for this purpose. If there is any serologic or psychiatric indication that she is suffering from dementia paralytica, she should immediately be treated with artificial fever, preferably by induced malaria.

Whatever type of neurosyphilis she may have, and whether fever is indicated, her treatment should certainly include the use of tryparsamide. This pentavalent arsenical drug may be safely given to patients sensitized against the arsphenamines.

No effort should be made to give the patient mapharsen, sulfarsphenamine or any other trivalent arsenical, since another attack of dermatitis will almost surely be precipitated. Acetarsone is wholly in the experimental stage in the treatment of syphilis and should not be used.

Compounds of either of the heavy metals mercury or bismuth alone, or in combination with each other, are inadequate to control neurosyphilis.

Current information as to the relative value of water soluble, oil soluble and insoluble oil suspensions of bismuth indicates that they are of approximately equal value, provided treatment is used specifically to take into account the factors of absorption and excretion. The water soluble products are absorbed and excreted so rapidly that treatment should be given either daily or every other day; the oil soluble products occupy an intermediate position and should be given twice a week; the insoluble oil suspensions are absorbed and excreted most slowly and may be given once a week.

INSULIN FOR DIABETIC PATIENT IN CORONARY DISEASE AND PNEUMONIA—HIGH PLASMA CHOLESTEROL

To the Editor:—A woman, aged 60, affected by mild diabetes with fasting blood sugar 185, is on a restricted carbohydrate diet. On account of her heart condition—incipient sclerosis of the coronary arteries—it has been decided not to give insulin because of its damaging effects in these conditions. Recently she fell sick with influenza and bronchopneumonia and the problem was whether dietary rules such as the carbohydrate restriction should be disregarded during the acute illness. What can be done to lower the cholesterol content in the blood of this patient?

M.D., New York.

ANSWER.—Three questions are raised in this case:

1. Should the patient receive insulin? The inquirer does not say just what is meant by "incipient sclerosis of the coronary arteries." Insulin itself is not contraindicated in coronary sclerosis, although insulin reactions are dangerous. If a patient needs insulin he should receive it, but it is well to be particularly careful to keep the dose below the point at which insulin reactions may occur. If there is not much sugar in the urine, no great concern need be attached to a value of 185 mg. of sugar per hundred cubic centimeters of blood; but, if sugar is present in the urine, the patient should receive sufficient insulin to control the amount of sugar in the urine, particularly in the first specimen passed on arising.

2. How much attention should be paid to the diabetic diet during the period of an associated illness? This question arises not only in cases of infection of the upper part of the respiratory tract, as in this case, but also in such conditions as peptic ulcer and chronic ulcerative colitis. In general, it is possible to control diabetes with almost any type of diet that is necessary, and in those cases in which the diet for an associated condition is of more importance to the patient's health than the diet for diabetes the dietary regimen for diabetes should be disregarded and the diabetes should be controlled with the changed regimen. In

primers for diabetic patients, such as those written by Joslin and by Wilder, there are excellent suggestions for temporary dietary changes in cases of associated complicating illness.

3. What can be done to lower the concentration of cholesterol in the plasma? The concentration of cholesterol in this case is not stated. The relationship of plasma cholesterol and other plasma lipoids to diet has not yet been finally answered. There is strong experimental evidence that the concentration of lipoids in the plasma is definitely related to the amount of fat ingested, but almost all the studies have been made on animals, which ordinarily do not eat any fatty foods. Therefore it has been virtually impossible to reproduce these results in animals which eat a general diet such as is eaten by man. The belief in the importance of a high carbohydrate, low fat diet is subscribed to by many but is not accepted by other equally capable men; however, until this problem is settled, it probably is best to restrict the amount of fat in the diet in cases in which the concentration of lipoids in the plasma is high.

INK AS CAUSE OF NEURITIS?

To the Editor:—A man aged 20, a printer for four years, uses news black and job ink, every day, made by the International Printers' Ink Corporation. Is there anything in this ink that could cause neuritis? All known tests for the cause of neuritis have been made and are negative.

ONAL A. SALE, M.D., Neosho, Mo.

ANSWER.—Nothing in the types of inks mentioned is known to be a source of neuritis as the sole manifestation of injurious action. In some operations connected with printing, highly repetitive, stereotyped motion conceivably might lead to a neuritis. Likewise, some chemicals that might be used, such as type cleaning fluids, might provoke a neuritis on rare occasions. At times the drying fluid used in connection with offset printing may lead to sensitization and a neuritis is not entirely impossible.

PROBABLE DERMOID CYST OF NOSE

To the Editor:—A girl aged 3½ had at birth a small cyst on the middle of the bridge of the nose. This cyst contained a small amount of white, rather sebaceous, material when opened. It has not refilled and is represented at present only by a small pit or porelike depression in the skin in the bridge of the nose. What would be the best treatment for this small lesion? PHILIP T. HOLLAND, M.D., Bloomington, Ind.

ANSWER.—A cyst or cystlike lesion in the midline anywhere appearing at birth speaks for a developmental anomaly, most probably a dermoid cyst. At the midline of the nose it is not likely to be a branchial or thyroglossal cyst. Sebaceous cysts are not likely to occur at birth, though of course they are by no means impossible then.

It would be the conservative procedure to let this healed lesion alone, even though the present healing may be only temporary. If there should be a reactivation with refilling of the cyst, it would then be time enough to take action. The extent of the cyst wall would indicate itself better then and appropriate measures would secure its elimination.

MISSED ABORTION

To the Editor:—A young married woman last October had a rather heavy period. Thereafter she missed some periods and had others scantier and shorter than normal; she had morning nausea, enlargement of the breasts and abdomen, and a gain in weight. The gain corresponded to a normal pregnancy until January; it then remained stationary for two months and then she lost 4 pounds (1.8 Kg.). From October on she had no leukorrhea, fever or chills and felt well except for backache. Early in April she had cramps and flowed heavily for three days, and the physician who examined her said she needed a curettage because of the placental tissue of a miscarriage of October had remained and that a retroverted uterus would not have permitted her to be pregnant for any long period. Please comment on this, especially as to the possibility of the placenta remaining that long without causing trouble. M.D., Iowa.

ANSWER.—It is difficult to make a diagnosis from the information given. The patient could have been pregnant, the embryo dying after several months' development and the expulsion failing to take place. In the so-called missed abortions all the symptoms and signs of early pregnancy are present but disappear. The uterus becomes progressively smaller. The products of conception may remain in the uterine cavity for many months without producing symptoms. As a rule, no bleeding occurs during this time. Bleeding may begin when the uterine cavity begins to evacuate its contents.

It is likewise possible that the patient was not pregnant at any time but that the amenorrhea of several months was the result of an endocrine disturbance. Sometimes a corpus luteum cyst causes a period of amenorrhea.

It is possible for a patient to continue with a normal pregnancy in a retroverted uterus. Usually the position of the uterus is corrected before the third month of gestation when the organ ceases to be confined to the pelvis but rises above the brim into the abdomen. Only rarely does abortion occur as a result of a retrodisplacement.

If the uterus is normal in size and normal menstrual periods have returned, dilation and curettage are not indicated. On the other hand, if the patient has irregular periods of bleeding it may be well to perform this minor procedure.

INCUBATOR HUMIDITY

To the Editor:—Is the degree of humidity in the incubator for premature infants considered to be of much importance? If so, what is considered to be the proper humidity? CARL IRENEUS, M.D., Chicago.

ANSWER.—The degree of humidity in an incubator must, of necessity, vary, first with the size of the infant, second with the temperature of the infant, third with the temperature at which the bed is heated and fourth with the exchange of air within the bed itself. In practical experience a relative humidity varying between 40 and 50 degrees within the bed is desirable. It should be remembered that with higher temperatures the relative humidity should be lower than with a lower temperature atmosphere. A large infant furnishes more heat in a closed bed than does a small premature infant, and a patient with a high temperature and increased respiration gives off more moisture than one with normal temperature. A rapid exchange of air in the bed also tends to keep the humidity at a level more nearly that of the surrounding room temperature. With a free current of air passing in and out of the bed there is little need for concern as to the child's welfare unless the surrounding air is especially dry.

HYPERTROPHY OF HAIR AFTER PLASTER CAST

To the Editor:—What is the explanation given for hypertrophy of hair found on removal of plaster casts? M.D., New York.

ANSWER.—Others corroborate this observation. No controlled studies have been found bearing on the question. This leaves the explanation open to conjecture.

STERILIZATION OF COCAINE HYDROCHLORIDE SOLUTIONS

To the Editor:—In THE JOURNAL July 16 a query appears under the heading "Sterilization of Cocaine Hydrochloride Solutions." In 1886 I began using cocaine solution chiefly in surgical practice, but later on in eye operations. Learning almost at once that the solution was unstable and deteriorated rapidly, I did a lot of experimenting and found that the addition of three drops of carbolic acid to a solution of cocaine hydrochloride (of any given amount) in an ounce of distilled water not only kept it absolutely sterile but prevented decomposition and loss of anesthetic power. I used control experiments and found not the slightest change at the end of a year. I have used it extensively in eye enucleations, strabismus operations and various other operations on the eye with the most satisfactory results and entire freedom from infection. The only drawback is that the first instillation causes a little more smarting than when it is made with distilled water. Subsequent instillations are not felt. It forms a precipitate, however, with the procaine hydrochloride-sodium chloride solution of Labat and others. If the inquirer desires further information on the subject or on the preparation of homatropine, physostigmine (eserine) and the like used in eye treatments, he may be referred to the final paragraph on page 198 and to page 212 of my "Fifty Years a Country Doctor" (New York, E. P. Dutton & Co.), which was recently reviewed in THE JOURNAL. Information regarding the preservation of cocaine solutions is given there.

WILLIAM N. MACARTNEY, M.D., Fort Covington, N. Y.

STERILIZATION OF RUBBER GOODS

To the Editor:—Under the caption "Sterilization of Rubber Boots and Shoes" in THE JOURNAL, July 2, page 81, Dr. George M. Blank of Lorain, Ohio, asks for "the simplest and most effective method of sterilizing rubber boots." While I have not had occasion to sterilize rubber boots I do have occasion to use many times daily rubber apron finger cots for rectal, vaginal and other forms of physical examination. Formerly I had great difficulty in ascertaining how to sterilize as well as preserve them. About ten years ago I began to wash these rubber finger cots with running water and a hand hairbrush, and then in soap and water, and again in clear running water to wash off all the soap, and then keep them immersed in a small basin of 1:2,000 aqueous solution of mercury bichloride. This cleans and disinfects them, and the mercury solution apparently preserves the rubber so that instead of being thrown away after each use they can be used over and over again many times before showing evidence of deterioration. It is suggested that this be tried with other rubber goods and the results reported. PAUL R. STALNAKER, M.D., Houston, Texas.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

- ALABAMA: Montgomery, June 20-22. Sec., Dr. J. N. Baker, 517 Dexter Ave., Montgomery.
- ALASKA: Juneau, Sept. 6. Sec., Dr. W. W. Council, Box 561, Juneau.
- ARIZONA: Basic Science. Tucson, Sept. 20. Sec., Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson.
- ARKANSAS: Medical (Regular). Little Rock, Nov. 3-4. Sec., State Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana. Medical (Eclectic). Little Rock, Nov. 3. Sec., Dr. Clarence H. Young, 1415 Main St., Little Rock. Basic Science. Little Rock, Nov. 7. Sec., Mr. Louis E. Gebauer, 701 Main St., Little Rock.
- CALIFORNIA: Reciprocity. San Francisco, Sept. 14, and Los Angeles, Nov. 16. Written examination. Sacramento, Oct. 17-20. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.
- COLORADO: Denver, Oct. 5-7. Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.
- CONNECTICUT: Basic Science. New Haven, Oct. 8. Prerequisite to license examination. Address State Board of Healing Arts, 1895 Yale Station, New Haven. Medical (Regular). Hartford, Nov. 8-9. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. Medical (Homoeopathic). Derby, Nov. 8-9. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.
- DELAWARE: Dover, July 11-13. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.
- DISTRICT OF COLUMBIA: Basic Science. Washington, Dec. 26-27. Medical, Washington, Jan. 9-10. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.
- FLORIDA: Jacksonville, Nov. 14-15. Sec., Dr. William M. Rowlett, Box 786, Tampa.
- GEORGIA: Atlanta, Oct. 11-12. Joint-Sec., State Examining Boards, Mr. R. C. Coleman, 111 State Capitol, Atlanta.
- IDaho: Boise, Oct. 4-5. Commissioner of Law Enforcement, Hon. J. L. Balderston, 205 State House, Boise.
- ILLINOIS: Chicago, Oct. 18-20. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.
- INDIANA: Indianapolis, June 20-22. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.
- IOWA: Basic Science. Des Moines, Oct. 11. Corres. Sec., Mr. H. W. Grefe, Capitol Bldg., Des Moines.
- KENTUCKY: Louisville, Dec. 6-8. Sec., State Board of Health, Dr. A. T. McCormack, 620 S. Third St., Louisville.
- MAINE: Portland, Nov. 8-9. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.
- MARYLAND: Medical (Regular). Baltimore, Dec. 13-16. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. Medical (Homoeopathic). Baltimore, Dec. 13-14. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.
- MASSACHUSETTS: Boston, Nov. 8-10. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.
- MICHIGAN: Lansing, Oct. 12-14. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 202-3-4 Hollister Bldg., Lansing.
- MINNESOTA: Basic Science. Minneapolis, Oct. 4-5. Sec., Dr. J. Charnley McKinley, 126 Millard Hall, University of Minnesota, Minneapolis. Medical. Minneapolis, Oct. 18-20. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.
- MISSISSIPPI: Reciprocity. Jackson, December. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.
- MISSOURI: Kansas City, Oct. 18-20. State Health Commissioner, Dr. Harry F. Parker, State Capitol Bldg., Jefferson City.
- MONTANA: Helena, Oct. 4. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.
- NEBRASKA: Basic Science. Lincoln, Oct. 4-5. Dir., Bureau of Examining Boards, Mrs. Clark Perkins, State House, Lincoln.
- NEVADA: Carson City, Nov. 7-9. Sec., Dr. John E. Worden, Capitol Bldg., Carson City.
- NEW HAMPSHIRE: Concord, Sept. 15-16. Sec., Board of Registration in Medicine, Dr. Fred E. Clow, State House, Concord.
- NEW JERSEY: Trenton, Oct. 18-19. Sec., Dr. James J. McGuire, 28 W. State St., Trenton.
- NEW MEXICO: Santa Fe, Oct. 10-11. Sec., Dr. Le Grand Ward, 135 Palace Ave., Santa Fe.
- NEW YORK: Albany, Buffalo, New York, and Syracuse, Sept. 19-22. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.
- NORTH CAROLINA: Reciprocity. December. Sec., Dr. William D. James, The Hamlet Hospital, Hamlet.
- NORTH DAKOTA: Grand Forks, Jan. 3-6. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.
- OKLAHOMA: Basic Science. Oklahoma City, Nov. 30. Sec. of State, Hon. Frank C. Carter, State Capitol Bldg., Oklahoma City. Medical. Oklahoma City, Dec. 14. Sec., Dr. James D. Osborn Jr., Frederick.
- OREGON: Basic Science. Portland, Nov. 19. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.
- PENNSYLVANIA: Philadelphia, January. Sec., Board of Medical Education and Licensure, Dr. James A. Newpher, 400 Education Bldg., Harrisburg.
- Puerto Rico: Santurce, Sept. 6-10. Sec., Dr. O. Costa Mandry, Box 3854, Santurce.
- RHODE ISLAND: Providence, Oct. 6-7. Chief, Division of Examiners, Mr. Robert D. Wholey, 366 State Office Bldg., Providence.
- SOUTH CAROLINA: Columbia, Nov. 8. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.
- SOUTH DAKOTA: Pierre, Jan. 17-18. Director of Medical Licensure, Dr. B. A. Dyar, State Board of Health, Pierre.
- VERMONT: Burlington, Feb. 14. Sec., Board of Medical Registration, Dr. W. Scott Nay, Underhill.
- VIRGINIA: Richmond, Dec. 14-16. Sec., Dr. J. W. Preston, 30½ Franklin Road, Roanoke.
- WEST VIRGINIA: Bluefield, Oct. 31-Nov. 2. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.
- WISCONSIN: Basic Science. Madison, Sept. 24. Sec., Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. Medical. Madison, Jan. 10-14. Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.
- WYOMING: Cheyenne, Oct. 3 (probable date). Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

NATIONAL BOARD OF MEDICAL EXAMINERS
SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, August 27, page 867.

Alabama June Examination

Dr. J. N. Baker, secretary, Alabama State Board of Medical Examiners, reports the examination held at Montgomery, June 28-30, 1938. The examination covered ten subjects and included 100 questions. Twenty-nine candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Emory University School of Medicine.....	(1938)	79.5, 88, 89.4, 89.9	83.4,
University of Georgia School of Medicine.....	(1938)		86.5
Northwestern University Medical School.....	(1938)		90.7
Rush Medical College.....	(1937)	88.5, (1938)	85.7
School of Medicine of the Division of Biological Sciences.....	(1937)		92.2
Tulane University of Louisiana School of Medicine.....	(1938)	84.6, 86.7, 87.3, 88, 90.9	82.5,
Harvard University Medical School.....	(1934)	89, (1937)	92.5
Washington University School of Medicine.....	(1938)	85.4, 90.3	
Cornell University Medical College.....	(1938)	87.5, 90.6	
University of Oklahoma School of Medicine.....	(1937)		84.9
Jefferson Medical College of Philadelphia.....	(1937)		89.6
University of Pennsylvania School of Medicine.....	(1936)		89.2
University of Tennessee College of Medicine.....	(1937)		76.3
Vanderbilt University School of Medicine.....	(1938)		88
Dalhousie University Faculty of Medicine.....	(1937)		81.8
University of Western Ontario Medical School.....	(1933)		90.3

Fifteen physicians were licensed by reciprocity from May 9 through July 27. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Howard University College of Medicine.....	(1935)		Kansas
Northwestern University Medical School.....	(1934)		Ohio
University of Louisville School of Medicine.....	(1937)		Kentucky
Tulane University of Louisiana School of Medicine.....	(1934), (1935), (1936), (1937)	Louisiana	
Detroit College of Medicine and Surgery.....	(1919)		Michigan
University of Michigan Medical School.....	(1927)		Michigan
St. Louis University School of Medicine.....	(1935)		Missouri
Washington University School of Medicine.....	(1936)		Missouri
Medical College of the State of South Carolina.....	(1937)		S. Carolina
Vanderbilt University School of Medicine.....	(1932), (1935)		Tennessee
Medical College of Virginia.....	(1920)		Virginia

Mississippi June Report

Dr. Felix J. Underwood, executive officer, Mississippi State Board of Health, reports the written examination held at Jackson, June 22-23, 1938. The examination covered twelve subjects and included ninety-six questions. An average of 75 per cent was required to pass. Thirty-two candidates were examined, thirty-one of whom passed and one failed. Sixteen physicians were licensed by reciprocity and one physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Arkansas School of Medicine.....	(1938)		84.3
Emory University School of Medicine.....	(1938)		87.9
Northwestern University Medical School.....	(1938)		90.1*
University of Louisville School of Medicine.....	(1938)		90.7
Tulane University of Louisiana School of Medicine.....	(1937)		84.6,
	88.4, (1938) 84.8, 87.4, 87.6, 87.9, 88.5		
University of Tennessee College of Medicine.....	(1935)		83.2,

Book Notices

The Foundations of Nutrition. By Mary Swartz Rose, Ph.D., Professor of Nutrition, Teachers College, Columbia University. Third edition. Cloth. Price, \$3.50. Pp. 625, with 116 illustrations. New York: Macmillan Company, 1938.

The last edition of this popular textbook was published five years ago. The author now has brought the material to date, while retaining all the charm and readability for which the earlier editions have been noted. A feature of the book is the historical treatment accorded each section. This material is written in a style which leaves the reader with a feeling that, in some way, he has been permitted a peek into the laboratories and clinics where classic researches have been developed. The book covers the entire field of nutrition. As an example of the thorough method of presenting a subject, the chapter on vitamin G can be regarded as more or less typical. In this chapter there are discussions of the discovery of vitamin G and the isolation of riboflavin, the importance of this factor in the promotion of growth and the maintenance of the health of the skin and eyes and the prevention of experimental cataract, the probable value of riboflavin in the maintenance of health and vigor of all ages and, finally, discussions of methods of measurement, food sources and requirements. The illustrations for this particular chapter include photographs of a chicken fed on a normal ration and another fed on a G-deficient diet, several charts of growth curves of rats fed on diets lacking in vitamin G, a good illustration of crystals of riboflavin, several pictures of rats showing signs of vitamin G deficiency, a curve showing the resumption of growth after a vitamin G-free diet in the rat, a picture of a turkey fed on a vitamin G-deficient diet, and showing eyelids stuck together and incrustation of the mouth and nostrils, a picture of cataract in rats, and an illustration of sixteen common foods in dishes, each food being represented by the portion that would supply approximately 50 units of vitamin G. There is a selected list of references at the end of the chapter. The same thorough treatment is given each topic. The book is copiously illustrated with well chosen charts, diagrams and reproductions of photographs. There are extensive tables of food values and other useful tables in the appendix. The book should be in the library of every person interested in foods and nutrition.

Studies on Biological Oxidation and Some of Its Catalysts (C, Dicarboxylic Acids, Vitamin C and P etc.). By Albert v. Szent-Györgyi, M.D., Ph.D., Professor of Medical and Organic Chemistry, University of Szeged, Acta Litterarum ac Scientiarum Reg. Universitatis Hung. Franciscus-Josephinae, Sectio Medicorum Tome IX, Fasc. 1. Redigunt: J. Baló, B. Miskolczy et St. Rusznyák. Paper. Price, 5 marks. Pp. 98, with 12 illustrations. Leipzig: Johann Ambrosius Barth; Budapest: Eggenbergische Buchhandlung Karl Rényi, 1937.

To many persons it may have been a matter of surprise that Szent-Györgyi was awarded a Nobel prize in 1937 chiefly for his work on biologic oxidations rather than for his better known work on the isolation of vitamin C. This little volume explains how the isolation of vitamin C was, in a sense, a by-product of investigations of the as yet incompletely understood mechanism of the oxidation of foodstuffs in tissues. Szent-Györgyi, who had discovered in animal tissues the catalytic nature of those dicarboxylic acids which contain four carbon atoms, investigated also oxidation systems in plant tissues. A substance having marked reducing properties was isolated from both plant (citrus fruit juices, cabbage leaves) and animal tissue (adrenal glands). This fundamental, widely distributed reducing agent of cells, either of animals or of plants, first was called hexuronic acid. Its antiscorbutic properties were not discovered until several years later. "From the very beginning," writes Szent-Györgyi, "I suspected ascorbic acid to be identical with vitamin C but my roaming life was unsuited for vitamin tests and moreover, somehow or other, vitamins were my pet aversion. Vitamins owe their great popularity to their paradoxical behavior, making us ill if we do not eat them, while all other substances make us ill only when we do eat them. What food must contain to be wholesome is a question of primary interest to the cook rather than to the scientist. Accordingly the appreciation of results of

vitaminology are often out of all proportion to their scientific importance. Moreover, the vitamin nature of ascorbic acid could not contribute much to its real scientific interest, since its importance and presence in plant and animal tissues has been demonstrated already."

The author goes on to write: "Two years later I was condemned to be professor and sent to the chair (of biochemistry) in Szeged. At the same time fate has sent me a clever collaborator, J. L. Svirbely, who has had some experience in vitamin C tests and brought with him the conviction that my ascorbic acid could not be vitamin C. All the same I made him test my old suspicion to see whether the small quantity of powder left in the bottom of one of my tubes was not the vitamin C. In November 1931 he had definite evidence that it was. At this time also Tillmans directed attention toward the possible identity. We did not publish until we could repeat our experiment on a large number of animals. Simultaneously King and Waugh reported the isolation of crystals from lemon juice which had antiscorbutic properties and seemed to be identical with ascorbic acid, that time 'hexuronic acid.'"

The present volume is thus a personal account, projected against a background of related work by other investigators, of the researches of Szent-Györgyi, whose labors have led to such diverse results as the isolation of vitamin C and the discovery of the catalytic nature of malic, oxalo-acetic, succinic and fumaric acids.

The Biological Standardisation of the Vitamins. By Katharine H. Coward, D.Sc., Head of Nutrition Department, Pharmaceutical Society of Great Britain. Cloth. Price, \$4.50. Pp. 227, with 41 illustrations. Baltimore: William Wood & Company, 1938.

This book supplies, in compact and readable form, much authoritative information which should be in the hands of all persons working in the field of biologic assay of the vitamins. It should also be interesting and valuable to those concerned solely with the interpretation of the results of biologic assay. The book is divided into two parts. Part I deals with the description and evaluation of a variety of techniques proposed by different English and European investigators for the determination of vitamins A, B, C and D in terms of international units. This section provides many such useful and practical details as suggestions for the proper management of the rat colony, principles underlying the selection of satisfactory materials for use in both test and stock diets, prevention of "refection" and the most convenient methods for administration of the minute quantities of test materials which must frequently be employed. Part II deals with the mathematical estimation of the accuracy of the results obtainable for the different vitamins. The construction and proper use of curves of reference and response are clearly described by the author, who considers these devices economical of time and labor when the determination of the exact potency of the test material in numbers of international units per gram is required. An appendix contains a reprint of the report of the second conference on Vitamin Standardisation, London, 1934, in which the International Standard materials and the international units are defined. The usefulness of the book for American workers is, however, limited by the fact that many of the techniques commonly employed by American investigators for the determination of the various vitamins are not discussed. In the United States, for example, the official methods described by the U. S. Pharmacopeia for the assay of vitamins A and D in terms of U. S. P. (equivalent to international) units differ in some respects from those used abroad. Also the methods most frequently used for the biologic assay of vitamins B₁ and C; i. e., the Sherman-Chase rat-growth method and the Smith rat-curative method for vitamin B₁ and the Sherman, LaMer and Campbell method for vitamin C, differ in considerable detail from those described by Coward. The reader must bear in mind the fact that a variety of techniques may be used for the biologic assay of vitamins in terms of international units, the chief requirement being that a simultaneous test be run on the International Standard material whenever a determination of the vitamin potency of a substance is made. American workers will find it necessary to consult other references for the technical details of methods official in the United States.

Rancidity in Edible Fats. By C. H. Lea, B.Sc., Ph.D. Department of Scientific and Industrial Research, Food Investigation Special Report No. 46. Paper. Price, \$1.10. Pp. 230, with 38 illustrations. New York: British Library of Information; London: His Majesty's Stationery Office, 1938.

This report is a review of the present state of scientific knowledge concerning the development of rancidity in edible fats and fat containing foods. The author defines rancidity as the deterioration in odor and flavor which develops in fats or in the fatty constituents of foods on keeping. Rancidity may occur as a result of the absorption of odors, the action of enzymes present in tissues, the action of micro-organisms, atmospheric oxidation or any combination of these. The book contains a brief but adequate discussion of each of these subjects. Methods of detecting and measuring rancidity are described. There is also a discussion of antioxidants, including the recent work of Mattill and Musher and others, and a bibliography of references to the literature. The book contains an initial chapter on the chemistry of fats and a final chapter on rancidity in dairy products and in the fat of meat. This report should prove useful to persons concerned with the preservation of foods and it is a fitting addition to the splendid monographs that have been issued under the auspices of the Food Investigation Board.

The International Cancer Research Foundation Report of Activities During 1937. Paper. Pp. 143. Philadelphia: The Foundation, [n. d.]

This volume summarizes the investigations assisted or supported by the foundation during 1937. It is especially interesting to those who are concerned with cancer research. Progress of each piece of work is described in full and the publications based on such work which appeared during 1937 are listed. The table of contents indicates the senior member of the research group receiving the financial help of the foundation. Financial statements indicate that the organization paid grants of more than \$400,000 during 1937. The individual problems studied by the various workers cover all aspects of cancer research and are too numerous to mention even in general classifications. The funds of the organization are not used for buildings or equipment, but the foundation can accept gifts or contributions for such expenses. Between 35 and 50 per cent of the income of the foundation must be allotted outside the United States according to the by-laws of this foundation, which was organized in Philadelphia, June 8, 1932.

The Chicago Recreation Survey, 1937. Volume I: Public Recreation. Volume II: Commercial Recreation. A project sponsored jointly by the Chicago Recreation Commission and Northwestern University. By Arthur J. Todd, Chairman, Department of Sociology and Anthropology, Northwestern University. In collaboration with William F. Byron, Chairman, Division of Social Work, Northwestern University. Howard L. Vlerow, Director, Chicago Recreation Survey. Conducted under auspices of the Works Progress Administration, National Youth Administration and Illinois Emergency Relief Commission. Boards. Pp. 268; 167, with illustrations. Chicago, 1937.

This voluminous report is the product of joint effort participated in by the Chicago Recreation Commission, Northwestern University, Works Progress Administration, National Youth Administration and Illinois Emergency Relief Commission. Volume I deals with public recreation, volume II with commercial recreation. In volume I will be found chapters dealing with the planning and historical aspects of public recreation, its administration, financing management, facilities, museums, forest preserves, facilities for golf and tennis, swimming, lagoons and harbors, public libraries and miscellaneous. Numerous charts, diagrams and maps in many colors illustrate and clarify the text. Tabulations abound, going into infinite detail as to numbers and character of equipment and personnel, as well as costs. Volume II deals with licensing and control of commercial recreation and with the various forms of these, such as motion picture theaters, legitimate, concert and operatic theaters, billiards and bowling establishments, baseball, basketball and football, boxing and wrestling, commercial health clubs, gymnasiums and natatoriums, horse racing, riding, polo and horse shows, bicycling and automobile racing, golf and tennis, ice sports and roller skating rinks, rental libraries, sight-seeing tours, observatories, air sight-seeing flights, excur-

sions, annual shows, conventions, radio, newspaper promotion stunts, amusement parks of every conceivable variety, ball-rooms and dancing schools, retail liquor dispensing establishments, and commercialized vice. Maps, charts and tabulations are numerous and comprehensive.

There is a tremendous amount of reference material in these volumes. The work should serve as a valuable record of conditions as they exist in 1938, and it points the way to intelligent and constructive planning for future development. The most significant correlation established in the report is one that might have been anticipated and which is shown most graphically in the maps; namely, organized vice runs parallel with poor housing, liquor establishments and commercial "recreation" of the poorer types, and absence of adequate recreational facilities of the better type.

An Introduction to Chemistry. By John Arrend Timm, Assistant Professor of Chemistry, Fellow of Trumbull College, Yale University. With a foreword by John Johnston, Director of Research, United States Steel Corporation. International Chemical Series, James F. Norris, Ph.D., Consulting Editor. Third edition. Cloth. Price, \$3.50. Pp. 568, with illustrations. New York & London: McGraw-Hill Book Company, Inc., 1938.

The author has attempted to stress the philosophy of chemistry. The subject matter is logically presented in a style intended for those whose main interest lies in some other field. The scientific method, chemical literature, practical applications of chemical research and the history of chemistry are elaborated only so far as these contribute toward a general education. Many modern concepts, such as acid-base theory, radiation, nuclear chemistry and vitamin chemistry, are included, together with the classic experiments and theories of chemistry. The text contains references to books and original publications for collateral reading sufficient to stimulate but not burden the reader. The book is well illustrated and clearly printed. The volume is not suited to those who seek detailed chemical information.

Van Nostrand's Scientific Encyclopedia. Cloth. Price, \$10. Pp. 1,234, with illustrations. New York: D. Van Nostrand Company, Inc., 1938.

A great volume of this type is an indication of the tremendous mass of scientific knowledge now assembled in many fields. In the development of this book ten contributing editors and eleven consulting editors have participated. Apparently the only physician concerned is Dr. R. Sterling Mueller, instructor in surgery in Columbia University. One finds many medical subjects rather inadequately treated. If one is to believe the initials at the end of the article on cancer, it was written by Warren K. Green, professor of astronomy at Amherst College, in collaboration with Dr. Mueller. Our absence of knowledge of certain phases of cancer would indicate that a professor of astronomy might be the ideal collaborator for such a purpose. The article dealing with carbuncles is written jointly by the geologist and the doctor because it turns out that a carbuncle is another name for a stone called a garnet. The discussion of syphilis makes no mention of the great campaign now under way in this country or of the standardized methods of treatment developed as a part of that campaign. Neither is there any reference to the gradually developing laws regulating marriage during syphilis. This volume offers sound information on most of the subjects that it discusses but not the type of information that one secures in encyclopedias in which great numbers of authorities take the responsibility for various branches of science.

Mount Sinai Hospital, Philadelphia: Diet Manual. Second edition. Paper. Pp. 87. Philadelphia, [n. d.].

The physician who is charged with prescribing a diet in any institution is between the difficulty of individualizing the diet for his patient and meeting the limitations set up by the needs of the occasion and the facilities of the institution. Thus it is important to have certain standards from which diets can be developed. There are a considerable number of books available which supply data concerning protein, carbohydrates and fats, mineral salts, vitamins and caloric value of ordinary portions of various foods. There are also a number of special works dealing with the development of diets for diabetic patients and those with dysentery, colitis,

epilepsy and other conditions. The diet list prepared by the Mount Sinai Hospital, Philadelphia, includes all these data in mimeographed form as well as a number of other diets which continued usage in that institution has indicated are most frequently demanded. Those wishing a standardized list of this character will find the Mount Sinai notations exceedingly practical and suggestive.

Physicians of The Mayo Clinic and The Mayo Foundation. Cloth. Price, \$10. Pp. 1,575, with portraits. Minneapolis: University of Minnesota Press; London: Oxford University Press, 1937.

This is the third of a series of volumes which have listed the physicians associated from time to time with the Mayo Clinic and the Mayo Foundation, providing for most of them a photograph, a brief biography and a bibliography. The volume thus constitutes an invaluable work of reference for all publishers and periodicals, since many of those concerned have made their names enviable as contributors to medical progress. The book is well arranged, nicely printed and in the mass of its material a useful work in the evaluation of the factors that make for medical success.

Milk and Nutrition: New Experiments Reported to the Milk Nutrition Committee. Part II: The Effects of Dietary Supplements of Pasteurized and Raw Milk on the Growth and Health of School Children (Interim Report). Paper. Price, 1s. 9d. Pp. 31. Shinfield, Reading, England: National Institute for Research in Dairying, 1938.

There are presented in this pamphlet the results of a study, conducted over a period of one school year, of the influence of milk on growth and health. The home diets of the children were not controlled. Four groups of 2,000 children each received supplements at school of, respectively, biscuits, one-third pint of pasteurized milk and two-thirds pint of either pasteurized or raw milk. It was found that the average child receiving milk grew slightly more in height and weight than the average child who did not receive supplements of milk at school. Children who received larger amounts of milk thrived somewhat better than those receiving smaller amounts. No significant difference was found with raw versus pasteurized milk. The differences between groups, however, are small, and the committee interprets this as evidence of improvements in the diets at home since Orr made his report in 1928.

Die Hypovitaminosen: Relative Vitaminmangel-Krankheiten in der Praxis. Von Prof. Dr. Richard Seyderhelm, Direktor der medizinischen Klinik am Hospital zum Heiligen Geist, Frankfurt a. M. Paper. Price, 8 marks. Pp. 156. Leipzig: Johann Ambrosius Barth, 1938.

Seyderhelm has produced a book which should be useful for clinicians who read German. Hypovitaminosis is considered to be either primary or secondary, primary when due to insufficient amounts of vitamins in the food and secondary when due to defective absorption or increased demands. The therapeutic use is discussed of preparations containing vitamins A, B, riboflavin and other members of the vitamin B complex, and vitamins C and D. Brief mention is made of vitamins E and P. A list of commercial vitamin preparations is provided. There is also a short table of foods which are useful as sources of the vitamins.

Artificial Light and Its Application. Commercial Engineering Department, Westinghouse Lamp Division, Westinghouse Electric & Manufacturing Company. Paper. Price, 75 cents. Pp. 258, with illustrations. Bloomfield, New Jersey, [n. d.].

This planographed report is an extensive discussion of artificial light and its application. There are chapters dealing with light sources, with "the language of lighting," photometry, light and vision, color, light control and lighting equipment, interior lighting design, industrial lighting, school lighting, commercial and public building lighting, display lighting, home lighting, farm lighting, floodlighting, recreational and sports lighting, architectural lighting, electrical advertising, street lighting and highway lighting, and lighting in the theater. The list of topics will suggest the wide range of interests to which this report should appeal. To the ophthalmologist, the physician who is a member of the school board, the school physician and the school administrator, the chapters dealing with light and vision and the lighting of school rooms should be especially useful, as should the discussion of photometry. The report is comprehensive and detailed, liberally illustrated with

photographs and diagrams, and accompanied by extensive tables, charts and plans for the application of artificial light under virtually every conceivable set of circumstances from the feed alley in a horse barn to the majestic façade of a governmental building. The Better Light-Better Sight activity of recent date, which has sharpened interest in the subject of lighting and its relation to vision, and the consequent stimulus to interest in sight conservation, should create a demand for information which this book is admirably calculated to supply. Reports of this character are an example of how industries may furnish valuable contributions to health and welfare while at the same time promoting their own commercial interests.

Petting-Wise or Otherwise? By Edwin Leavitt Clarke. Paper. Price, 25 cents. Pp. 32. New York: Association Press, 1938.

For patients who prefer to take their sex education with a sugar coating, this pamphlet may be recommended as far as it goes. The information is conveyed through recital of the conversation between two young persons, married and engaged in campus leadership activities, and an older married couple, both physicians, during a call by the former at the home of the latter. Like all writing in this field which singles out one phase of the sex question, such as masturbation or petting, it suffers from lack of balance, in that it does not tell the whole story. What it does tell is sound and adequate, though the technic renders it much more wordy than would have been necessary to convey the information in simple straightforward style. The persistence of this style of writing about sex seems to be an indication that not all readers are willing to take their facts straight, a fact which might be commended to the attention of supermodern writers who are not content to call a spade a spade but must add details.

Keesing's Medical Digest, January 1—March 31, 1938. Fabrikoid. Subscription price, £1.5s. per annum. London: Keesing's Medical Digest, Ltd., 1938.

This small book has a calendar on the first page, followed by two vacant pages for telephone numbers and ninety-six pages of abstracts of articles published recently in various medical journals. Then follow many blank pages on which the physician may record his visiting list, with a few pages to record obstetric engagements, adjacent to the dates of the last menstruation, first fetal movements, and when labor is expected. The last pages also are blank to record the amount of cash receipts. The book is of the loose leaf type, fitting between spring covers which, when sprung backward, permit the easy removal of all the contents and its replacement with new material.

On Thought in Medicine (Das Denken in der Medizin). By Hermann von Helmholtz. An Address delivered August 2, 1877, on the Anniversary of the Foundation of the Institute for the Education of Army Surgeons. Introduction by Arno B. Luckhardt. [Reprinted from *Bulletin of the Institute of the History of Medicine*, Vol. VI, No. 2, February, 1938.] Boards. Price, 75 cents. Pp. 27, with portrait. Baltimore: Johns Hopkins Press, 1938.

In 1877 von Helmholtz delivered an address on the anniversary of the foundation of the Institute for the Education of Army Surgeons. In his introduction to the reprinting of this address Professor Luckhardt indicates that universality is proved by the fact that this same address might well have been written to meet conditions in the world within the last few years. The essay "On Thought in Medicine" is a recapitulation of medical theories of the past and a demand for scientific evidence from the laboratory and the clinic as the basis for medical progress.

Leaves from a Surgeon's Case-Book. By James Harpole. Cloth. Price, \$2.75. Pp. 300. New York: Frederick A. Stokes Company, 1938.

The title almost expresses the character of this volume. It is written by a surgeon under a non de plume and is essentially a collection of anecdotes from medical practice, offering for the lay reader in this way educational material in an easily absorbable medium. There is not a sustained interest throughout the book but the casual reader will find that it offers so much of interest that he is likely to proceed gradually throughout the entire volume.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Death of Physician from Pneumonia Compensable.—The claimant's husband was surgeon-in-chief of the defendant hospital. On Jan. 29, 1933, at 12:30 a. m., he responded to an emergency call from the hospital. The weather was cold and windy, with snow and rain falling intermittently. The patient was found to be in an extremely critical condition, because of a bad fracture of the skull and a broken leg. According to the custom of the hospital, an incoming patient is observed in the dispensary, located in the basement, and if surgical attention is required he is removed to the operating room on the top floor of the hospital, unless the injury is of a very minor nature. The claimant's husband, evidently concluding that an immediate operation was necessary and that the patient should not be subjected to any avoidable disturbance, performed a major operation on the patient in the dispensary. The room temperature there was abnormally low, estimated as between 40 and 50 degrees. Although the physician, in the course of the operation requiring about an hour, had donned an extra gown, he had a severe chill. When the operation was completed, he was placed in a bed in the hospital and kept there the rest of the night. On January 31, in accordance with plans he had made, he started on a vacation but was taken ill en route and died in a hospital, February 28, "of influenza pneumonia and attending complications." The claimant sought compensation under the workmen's compensation act of Pennsylvania. The referee found that the death was the result of an accidental injury and awarded compensation, the award being affirmed by the workmen's compensation board. The court of common pleas reversed the finding of the board, and the claimant appealed to the superior court of Pennsylvania.

A nurse who assisted in the operation testified that she noticed that the physician's shoes and the bottom of his trousers were wet and that he told her "his car got stuck in the snow, in the slush, on the way up and he had to shovel his way out." The admission of this testimony was objected to on the ground that it was hearsay. Declarations of an injured person, said the court, made at or so near the scene of the accident and so shortly after it happened as to preclude the presumption that they were the result of premeditation or design are generally held to be admissible. Here the evidence did not warrant the slightest suspicion that the physician's statement was uttered with premeditation or with an ulterior purpose in mind. While it did not definitely appear, the court thought it could be reasonably assumed that a very brief time intervened between the physician's departure from home and his arrival at the hospital and that the statement was made to the first person he met. Furthermore, in the court's opinion the proof of an accidental injury did not depend entirely on the nurse's alleged hearsay testimony; there was competent evidence that she saw the physician's wet clothing. Owing to the inclement weather, with "awful driving conditions," it could readily be inferred from what the nurse observed that something of an unusual nature had happened to the physician on his way to the hospital. It was entirely safe to say that, in the ordinary course of events, a surgeon does not go to a hospital where he is to operate, with wet trousers and shoes. If such a thing occurs, one naturally concludes that he had some unusual experience.

Direct evidence of the cause of the physician's wet clothing was not necessary; it could be established by circumstantial evidence. Here, the court said, the physician met with an accident before he entered the dispensary. In view of the patient's critical condition, prompt action was evidently necessary. The humanitarian endeavor to save the life of a person who was so seriously injured could not be regarded in any other sense than one of absolute necessity, and not as a voluntary act performed under usual conditions. If pneumonia is contracted

by exposure to cold or water, under conditions which usually prevail, the general rule is that it is not compensable. On the other hand, if one is exposed in the course of his employment to unusual conditions, and pneumonia results therefrom, there is an accidental injury. The court thought it unnecessary to discuss the medical testimony but expressed the view that it was sufficient to establish the causal connection between the accident and the death. The proof of a wetting established a mishap—an untoward event, which was the super-inducing cause of death. It was followed by exposure in an unusually cold room, where at that time it was vitally necessary for the physician in the course of his employment to perform an operation. The facts, in the opinion of the court, were sufficient to support the finding of the referee that there was an accidental injury within the meaning of the workmen's compensation act. The judgment of the court below was therefore reversed and the record remitted with directions for a judgment to be entered on the findings and conclusions of the workmen's compensation board.—*Roth v. Locust Mountain State Hospital (Pa.)*, 196 A. 924.

Basic Science Acts: Health Lecturer Practices the Healing Art.—The defendant, Vivi Ann Mielke, also known as Vivi Ann Wyntor, was charged with practicing healing without a valid certificate of registration in the basic sciences. The trial court certified to the Supreme Court of Minnesota the following question: "Does the amended information as filed charge a public offense under the Basic Science Act of the State of Minnesota as set out in section 5705-1 et seq., Mason's Minnesota Statutes for the year 1927?"

The amended information charged the defendant with advertising herself as an assistant and staff lecturer for an osteopath of Kansas City and that she would give free daily lectures at specified times in a hotel in St. Paul. During the lectures the defendant solicited women present to attend a lecture course which was to follow immediately, for which a fee was charged. A number of women attended and paid the fee, and during the lectures certain products or concoctions were described by the defendant and their uses and values discussed. Circulars were distributed by and under the direction of the defendant which further described the products. It was announced, during the lectures, that the defendant had such products for sale and she suggested and recommended their purchase by the hearers. From the sales the defendant derived a commission of 55 per cent, the remainder going to the Kansas City osteopath, who held no license to practice healing in Minnesota. Among the products offered for sale were certain tablets claimed to contain red bone marrow and spleen and labeled "Useful in Secondary Anemia." The defendant also was charged with having sold female hormone tablets in connection with her lectures.

The basic science act of Minnesota, said the Supreme Court, forbids the practice of healing without first having obtained a certificate of proficiency in the basic sciences. By the terms of the act the basic sciences are defined to include anatomy, physiology, pathology, bacteriology, hygiene and chemistry so far as they relate to the human system or mind. The practice of healing is defined as including any person who shall in any manner for fee, gift, compensation or reward, or in expectation thereof, engage in the diagnosis, analysis, treatment, correction or cure of any disease, injury, defect, deformity, infirmity, ailment or affliction of human beings, or who for any fee suggests, recommends or prescribes any medicine or cure thereof. The defendant did not attack the constitutionality of the basic science act but asserted that as it applied to her or to the acts charged against her it infringed on her constitutional rights and that there was no relation between the requirements of the basic science act and the protection of the public as applied to her situation. With this contention, however, the Supreme Court disagreed. It is essential to the public health and safety, the court pointed out, that persons who, for compensation, suggest, recommend or prescribe medicine or treatment for the correction or cure of human ailments have a basic understanding of the subjects required by the basic science act. It is within the police power of the state so to require. According to the information lodged against

her, the court continued, the defendant induced women to come to lectures for which she charged a fee and for those who had menstrual troubles she suggested and recommended tablets which she had for sale for correction and cure of their affliction. Her conduct, therefore, came squarely within the basic science act. The requirements of that act are germane to the safety and health of the public in the treatment of such ailments as those for which the defendant sold and recommended her tablets and medicines. Such being the case, no constitutional right of the defendant was infringed on.

In the opinion of the Supreme Court, therefore, the question certified by the trial court should be answered in the affirmative.—*State v. Mielke (Minn.)*, 277 N. W. 420.

Dental Practice Acts: Board Exercises Administrative Functions in Revoking License.—A state board of dental examiners, said the district court of appeal, first district, division 1, California, exercises discretionary administrative functions, not judicial functions, in revoking licenses to practice dentistry. Neither a writ of prohibition nor a writ of certiorari, therefore, may be utilized to obtain a court review of a revocation order.—*Jacobs v. Board of Dental Examiners (Calif.)*, 75 P. (2d) 96.

COMING MEETINGS

- Academy of Physical Medicine, Washington, D. C., Oct. 24-26. Dr. Herman A. Osgood, 144 Commonwealth Ave., Boston, Secretary.
- American Academy of Ophthalmology and Oto-Laryngology, Washington, D. C., Oct. 9-14. Dr. William P. Wherry, 107 South 17th St., Omaha, Executive Secretary.
- American Association for the Study of Goiter, Washington, D. C., Sept. 12-14. Dr. W. Blair Mosser, 133 Biddle St., Kane, Pa., Secretary.
- American Association for the Study of Neoplastic Diseases, Washington, D. C., Sept. 8-10. Dr. Eugene R. Whitmore, 2139 Wyoming Ave. N.W., Washington, D. C., Secretary.
- American Association of Obstetricians, Gynecologists and Abdominal Surgeons, White Sulphur Springs, W. Va., Sept. 22-24. Dr. James R. Bloss, 418 Eleventh St., Huntington, W. Va., Secretary.
- American Association of Railway Surgeons, Chicago, Sept. 19-21. Dr. Daniel B. Moss, 547 W. Jackson Blvd., Chicago, Secretary.
- American College of Surgeons, New York, Oct. 17-21. Dr. George W. Crile, 40 East Erie Street, Chicago, Chairman, Board of Regents.
- American Congress of Physical Therapy, Chicago, Sept. 12-15. Dr. Richard Kovacs, 1100 Park Ave., New York, Secretary.
- American Hospital Association, Dallas, Texas, Sept. 26-30. Dr. Bert W. Caldwell, 18 East Division St., Chicago, Executive Secretary.
- American Public Health Association, Kansas City, Mo., Oct. 25-28. Dr. Reginald M. Atwater, 50 West 50th St., New York, Executive Secretary.
- American Roentgen Ray Society, Atlantic City, N. J., Sept. 20-23. Dr. Carleton B. Peirce, University Hospital, Ann Arbor, Mich., Secretary.
- Associated Anesthetists of the United States and Canada, New York, Oct. 17-21. Dr. F. H. McMechan, 318 Hotel Westlake, Rocky River, Ohio, Secretary General.
- Association of Military Surgeons of the United States, Rochester, Minn., Oct. 13-15. Dr. H. L. Gilchrist, Army Medical Museum, Washington, D. C., Secretary.
- Central Association of Obstetricians and Gynecologists, Minneapolis, Oct. 6-8. Dr. William F. Mengert, University Hospitals, Iowa City, Secretary.
- Clinical Orthopedic Society, Nashville, Tenn., and Birmingham, Ala., Oct. 7-8. Dr. H. Earle Conwell, 215 Medical Arts Bldg., Birmingham, Ala., Secretary.
- Colorado State Medical Society, Estes Park, Sept. 7-10. Mr. Harvey T. Sethman, 537 Republic Bldg., Denver, Executive Secretary.
- Delaware, Medical Society of, Dover, Oct. 10-12. Dr. Allan V. Gilliland, Smyrna, Secretary.
- Idaho State Medical Association, Sun Valley, Sept. 6-10. Dr. Harold W. Stone, 105 North Eighth St., Boise, Secretary.
- Indiana State Medical Association, Indianapolis, Oct. 4-6. Mr. Thomas A. Hendricks, 23 East Ohio St., Indianapolis, Executive Secretary.
- Kentucky State Medical Association, Louisville, Oct. 3-6. Dr. Arthur T. McCormack, 620 South Third St., Louisville, Secretary.
- Michigan State Medical Society, Detroit, Sept. 19-22. Dr. L. Fernald Foster, 311 Center Ave., Bay City, Secretary.
- Mississippi Valley Medical Society, Hannibal, Mo., Sept. 28-30. Dr. Harold Swanberg, 510 Main St., Quincy, Ill., Secretary.
- Nevada State Medical Association, Reno, Sept. 23-24. Dr. Horace J. Brown, 120 N. Virginia St., Reno, Secretary.
- Omaha Mid-West Clinical Society, Omaha, Oct. 24-28. Dr. J. D. McCarthy, 107 South 17th St., Omaha, Secretary.
- Pacific Association of Railway Surgeons, Los Angeles, Oct. 7-8. Dr. W. T. Cummins, Southern Pacific General Hospital, San Francisco, Secretary.
- Pennsylvania, Medical Society of the State of, Scranton, Oct. 3-6. Dr. Walter F. Donaldson, 500 Penn. Ave., Pittsburgh, Secretary.
- Vermont Medical Society, Burlington, Oct. 6-7. Dr. B. F. Cook, 154 Bellevue Ave., Rutland, Secretary.
- Virginia, Medical Society of, Danville, Oct. 4-6. Miss Agnes V. Edwards, 1200 East Clay St., Richmond, Secretary.
- Wisconsin, State Medical Society of, Milwaukee, Sept. 14-16. Mr. J. G. Crownhart, 119 East Washington Ave., Madison, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Clinical Pathology, Baltimore

8: 383-470 (July) 1938

- Clinical Pathology Today. C. W. Maynard, Pueblo, Colo.—p. 383.
Elliptic Erythrocytes in Human Blood. J. K. Miller and M. A. Lucas, Louisville, Ky.—p. 391.
*Leukocytosis Associated with Acute Inflammation. A. Nettleship, Nashville, Tenn.—p. 398.
Focal Fatty Change of Liver and Focal Cirrhosis. H. L. Stewart, D. R. Morgan and V. L. Sprenkel, Philadelphia.—p. 405.
Cystadenoma Lymphomatosum. A. W. Freshman and S. K. Kurland, Denver.—p. 422.
Syphilis as Factor in Bioscopic Diagnosis of Adult Cervical Lymphadenopathy. H. Fox, Philadelphia.—p. 431.
Tularemia of the Human Breast. M. J. Kilbury and S. C. Fulmer, Little Rock, Ark.—p. 436.
Disseminated Echinococcosis. O. O. Williams, San Francisco.—p. 442.

Leukocytosis with Acute Inflammation.—Nettleship studied the relation of acute inflammatory lesions to the concurrent leukocytosis by producing small lesions in the skin of the rabbit. Streptococci introduced into the skin of the normal rabbit produced acute inflammation accompanied by an early severe, prolonged leukocytosis. Cytoplasmolysis of leukocytes at the site of injection set in within two hours after injection and became more marked during the first twenty-four hours of inflammation, at which time the most rapid increase of leukocytes occurred. The cytoplasm of the leukocytes was the only tissue which necrosed early. Necrosis of the other tissues involved in the abscess did not occur to any extent until after twenty-four hours. The mechanism which may be responsible for generalized leukocytosis with acute inflammation is that some breakdown product from the action of the injuring agent on peripheral tissue diffuses into the blood stream to cause leukocytosis and hyperplasia of the bone marrow.

American Journal of Diseases of Children, Chicago

56: 1-234 (July) 1938

- Past Presidents of the American Pediatric Society (1888-1938): President's Address. K. D. Blackfan, Boston.—p. 1.
Vitamin A, Carotene and Vitamin C Content of Canned Milk. O. Meulemans and J. H. De Haas, Batavia, Java, Netherland East Indies.—p. 14.
Hepatomegaly in Juvenile Diabetes Mellitus Treated with Pancreatic Extract. H. G. Grayzel and L. S. Radwin, Brooklyn.—p. 22.
Size of the Heart in Healthy Children: Roentgen Measurements of Cardiac Area and Transverse Diameter for Sixty-Seven Children Between Birth and Age of Six Years. M. M. Maresh and A. H. Washburn, Denver.—p. 33.
Basal Metabolism of Undernourished Girls. F. B. Talbot, Boston.—p. 61.
*Serum Cholesterol in Patients with Rheumatic Fever: Further Study. F. M. Offenkrantz, Newark, N. J.—p. 67.
Respiratory Metabolism in Infancy and in Childhood: XXI. Daily Water Exchange of Normal Infants. S. Z. Levine, M. A. Wheatley, T. H. McEachern, H. H. Gordon and E. Marples, New York.—p. 83.
Acute Infectious Gingivostomatitis ("Vincent's Stomatitis"). W. C. Black, San Diego, Calif.—p. 126.

Serum Cholesterol in Rheumatic Fever.—Offenkrantz determined the serum cholesterol of 100 patients with rheumatic fever. Forty-nine of these were used as control subjects, since they had no evidence of rheumatic activity at the time. Evidence of such activity consisted of elevation of the leukocyte count above 10,000 per cubic millimeter, an erythrocyte sedimentation rate above 12 mm. per minute and increasing cardiac damage. The mean total value of the serum cholesterol (and standard deviation) was 181.9 ± 23.5 mg. per hundred cubic centimeters; the mean value of the free serum cholesterol was 50.5 ± 7.4 mg.; the mean percentage of free cholesterol was 27.3 ± 2.23 . Of the remaining fifty-one patients, five died. Analyses of serum

cholesterol one day before or ten minutes after death revealed severe depletion of the cholesterol ester and only slight lowering of the free cholesterol level, so that the percentage of free cholesterol rose above 30 in each instance. In eleven children who seemed to suffer activity of the rheumatic fever throughout the period (two summers) of observation the total cholesterol levels of the serum seemed to be definitely lowered and the percentage of free cholesterol elevated, so that the depletion was ascribed to the ester fraction. In twelve other patients the status of the disease fluctuated, periods of rheumatic inactivity being interrupted by flare-ups. The periods of activity again showed the lowered serum cholesterol level with the elevated percentage of free cholesterol (loss of ester). A general inverse relation was noted between the severity of the ester depletion (with a rise in the percentage of free cholesterol) and the sedimentation time. In nine cases, periods of cardiac decompensation were associated with the rheumatic infection. During such periods of failure the flare-up failed to produce the usual rise in the percentage of free cholesterol, although there was a moderate fall in the total cholesterol values. A similar situation seemed to prevail in seven cases in which a fluctuating status of the disease was complicated by a positive Mantoux reaction, though in six there was no evidence of active tuberculosis. Five instances are cited in which unusually high values for total cholesterol prevailed, despite activity of the disease. Possibly a psychiatric-functional status is associated with a particular type of cholesterol level in the blood.

Erythroblastosis. L. M. Hellman and A. T. Hertig, Boston.—p. 137.

Chemical Test for Pregnancy.—Savage and his associates made frequent examinations of the urine, blood pressure, eye-grounds, chemical determinations of the blood and renal function of fifty-eight toxemic patients admitted to the University Hospital in the last trimester of pregnancy. Twenty-four hour urine specimens were collected and estrogenic determinations were made. A few normal cases were included in order to establish normal levels of estrogenic excretion. A modification of the Schmulovitz and Wylie test for the chemical diagnosis of pregnancy by the detection of estrogen in the urine was devised. The procedure follows the principles of the original test with a few minor changes but uses only one tenth of the twenty-four hour specimen of urine. A marked reduction in the time required for the laboratory performance of this test, of from twenty-four to thirty hours to four hours, has thereby been achieved. Excretion of estrogen is expressed in terms of the "ferric chloride number," which is obtained as follows: The final colored alcoholic layer containing the estrogen extracted from the specimen of urine is filtered into a colorimeter cup and set at 10 mm. and is com-

pared with a standard 33 per cent ferric chloride solution, the reading of which is the ferric chloride number. The final reading in millimeters is multiplied by 10, and the factor 9 (the blank error is 1 mm.) is subtracted to give the final ferric chloride number. The excretion of estrogen expressed as ferric chloride numbers was 87.16 in six normal pregnant subjects, 47.05 in twenty-six patients with chronic nephritis complicating pregnancy and 40.03 in twenty-six cases of preeclampsia. Nine patients received 10,000 international units of theelin intramuscularly on each of three successive days and no improvement took place which could be ascribed directly to the hormone therapy.

Bilirubin Test in Toxemia of Pregnancy.—Lyon determined the function of the liver by the bilirubin elimination method in twenty cases of abnormal pregnancy (eclampsia, preeclamptic toxemia, nephritic toxemia, vomiting of pregnancy and premature separation of the placenta). The average retention was 11.8 per cent. He states that toxemias of pregnancy cannot be nosologically arranged on the basis of the bilirubin hepatic function test. However, the procedure is probably the most readily adaptable measure of the labile and manifold functioning liver. As such it may be of value together with renal function tests to aid in establishing a delimiting zone between the nephritic and preeclamptic toxemias.

American Journal of Public Health, New York

28: 807-906 (July) 1938

- Investigation of Early Syphilis. W. T. Clark and C. A. Sargent, Buffalo.—p. 807.

Endocrines and the Breast.—Birnberg and his associates treated fourteen cases of various breast dyscrasias (pain, nodules). Investigation included serial determinations of the gonadotropic substance and theelin and endometrial biopsies. There were eight cases of theelin deficiency, two of increased theelin production, two cases of deficiency of the corpus luteum hormone, one case of hypothyroidism and one of gynecomastia. The patients responded to therapy with the specific hormone shown to be lacking.

Clinical Results with Maggot Jelly.—During the last three years Livingston has used a surgical jelly containing the active maggot principle in the treatment of indolent ulcers of all types, carbuncles, boils, abscesses, compound fractures, burns of all types, preoperative and postoperative treatment of hemorrhoids, anal fissures and fistulas, cutaneous lesions with or without infection, infections of the cervix and genito-urinary tract and cutaneous grafts. The jelly is efficient, he believes, in chronic infections which are slow to heal and in which relief from local irritation is important and growth stimulation a necessity. The jelly, as the result of its chemical and its 5 per cent maggot content, relieves irritation and pain and is growth stimulating. In abscesses, boils and carbuncles a more rapid localization of the lesion and rapid postoperative healing occurred. Quick relief from pain, increased sloughing and earlier healing ensued in the various burns. In anal fissures and fistulas, healing was more rapid and the convalescence less painful after surgery. When the jelly is used preoperatively in hemorrhoids, bleeding is checked, irritation is relieved and spasm of the sphincter is released. When used postoperatively there are more rapid healing and less painful convalescence. More rapid granulation than with other ointments or jellies and relief from pain is obtained in indolent ulcers. Relief from irritation, softening of lesions, healing of fissures and dissolution of scaling occur in cutaneous lesions.

Ascorbic Acid of Blood in Alcoholic Psychoses.—Alexander and his associates determined the ascorbic acid content of the plasma in 106 patients suffering from alcoholic psychoses and fifty-eight psychotic subjects, as controls. The essential difference between the subjects used as controls and the group of patients with alcoholic psychoses was that the latter presented a history of severe alcoholism of long standing with, presumably, a poor dietary regimen. The average ascorbic acid value for the sixty-five patients with alcoholic psychoses with polyneuritis was 0.576 mg. per hundred cubic centimeters, for the eighteen patients with alcoholic psychoses with slight or no polyneuritis the average ascorbic acid value for the plasma was 0.559 mg. per hundred cubic centimeters, and in twenty-three patients in whom the psychoses were only possibly precipitated by alcoholism the average ascorbic acid content of the plasma was 0.92 mg. per hundred cubic centimeters. The patients used as controls who were studied shortly after admission had an average for the ascorbic acid content of the plasma of 0.893 mg. per hundred cubic centimeters. Control patients who by refusing food had decreased their vitamin C intake and aged persons with psychoses had ascorbic acid values in the range of those for subclinical scurvy.

Dangerous Effects of Colloidal Thorium Dioxide.—Stuck and Reeves carried out experiments on cats, dogs and monkeys demonstrating hydrocephalus, precipitation and concentration of thorium dioxide (thorotrast) in the dependent parts, radioactivity and little if any elimination. In addition, the distribution of the compound was observed in the subarachnoid spaces by x-ray and histologic methods and its excretion from the subarachnoid space was studied. When the compound is injected into an animal, the material is treated as a foreign body, picked up by cells of the reticulo-endothelial system and stored. Its prolonged storage in the tissues of the body leads to mild and later to intense fibrosis. In white rats this has been followed by sarcoma. The great specific gravity of this substance is important when it is injected into the subarachnoid space, where it tends to become concentrated in the dependent portions. Of the three ionizing rays emitted by thorium, the alpha ray (or particle) is by far the most destructive. Its destructive action appears to be due to its intense ionization. Since the effect of the alpha ray is blotted out by less than 1 mm. of tissue, it is only by the injection or ingestion of radioactive substances that this ray becomes important. Hydrocephalus has been demonstrated in cats, dogs and monkeys after spinal, cisternal and ventricular injections of colloidal thorium dioxide. After ventricular injection no excretion of this material from the cranial cavity could be shown by x-ray or electroscopic examination of excreta and microscopic study of tissues. Because of the permanence of colloidal thorium dioxide in the subarachnoid space, with the continuous opportunity for its radioactive destructive effect and the development of areas of fibrosis and cicatrices, the clinical application of the material for encephalography and ventriculography is dangerous.

Preoperative Management of Streptococcal Mastoiditis.—In mastoiditis in the course of an epidemic of influenza, of infection of the upper part of the respiratory tract or of a specific fever, according to Atkinson, the organism is nearly always a streptococcus of a virulent strain, usually hemolytic. A serious complication has never been warded off in a case of streptococcal infection by premature surgical intervention. The onset of complications is only hastened by surgical intervention before the infection has been brought under control and localized. Patients with mastoiditis are suffering, at the best, from bacteremia, if not active septicemia and they need physical and mental rest. Nothing can give that to them better than morphine. The diet is fluid, and extra fluid should be forced. Local heat should be used to relieve pain and to increase the blood supply. Specific serum is used in streptococcal disease. The serum must be polyvalent and of known potency and the dose must be adequate. In an adult with a severe infection 40 cc. intravenously is not too much for an initial dose. Serum should be continued in half doses, intramuscularly, at first daily and then every second day until the infection is brought under control. Nucleic acid stimulates leukocytosis and may be given intramuscularly every second day, in alternation with serum. Strychnine and sodium cacodylate can be added for their tonic effects. In the absence of a satisfactory serum, blood transfusion should be employed and preferably an immunotransfusion. The quantity given should not be more than 250 cc. for an adult, for it is not difficult to overload an acutely intoxicated heart. Sulfanilamide and allied compounds must be used with discretion

and with due appreciation of their limitations. There is so far no convincing evidence that the drug is of value in combating any streptococcus that is not hemolytic. From seven to ten days after the onset of the infection of the mastoid a change begins to be apparent in the patient. He who previously has been apathetic and listless becomes bright and alert; the sallow skin becomes clear, the dry, furred tongue clean and moist, the temperature falls from 103 or 104 F. to normal in the morning and 100 to 101 F. in the evening, while the pulse steadies, the blood picture (which possibly showed leukopenia at first) now shows leukocytosis and the tenderness of the mastoid, which was diffuse, becomes more definitely localized. The changed clinical picture should be allowed to stabilize itself and the temperature to settle or to take on a definite swinging character for two or three days before operation is undertaken. Operation then will reveal the presence of pus, probably localized in a cavity, in any event with the limits of its extent clearly defined; the postoperative course will be smooth and free from anxiety, and healing will take place rapidly. Of nineteen patients operated on without delay from 1926 to 1931, eight had complications, three of whom died, while of fourteen patients treated expectantly between 1932 and 1935 only one had any complication and none died. The average length of stay in the hospital for the first group was thirty-three days, and that for the second only twenty-seven days.

Effect of Ascorbic Acid on Insomnia.—Maurer and his associates have given from 1 to 3 Gm. of ascorbic acid daily to more than 100 patients suffering from insomnia and other conditions without evidence of toxic effect. Overdosage produces sound sleep from which the patient may be aroused easily, followed by drowsiness during the day. This drowsiness, however, disappears within twenty-four hours after the ascorbic acid has been discontinued. Administration of ascorbic acid was discontinued immediately on reports or observation of "apparently normal" sleep and not resumed until after the subjects again reported or were observed to be having difficulty in sleep. The beneficial effects of ascorbic acid lasted from a day to more than a week and varied with different individuals.

Hypersensitiveness to Tobacco.—In order to determine the nature of the tissue response in patients with vascular disease Harkavy made biopsy studies of the area of skin reacting from the intracutaneous injections of tobacco extracts and wheals produced by saline and ragweed extracts used as controls in fifteen persons. Ten suffered from thrombo-angiitis obliterans, one had migrating phlebitis, one had coronary artery disease and three were surgical patients used as normal controls. Each of these patients was tested simultaneously with six different types of tobacco as well as ragweed, timothy, horse dander extracts and Coca's diluting fluid. Positive cutaneous reactions to tobacco were obtained in the twelve patients and in one of the control subjects. The type of reaction was characterized by an immediate urticarial wheal in ten of the patients and a delayed type of reaction in two. Of the three controls, one showed an immediate reaction to tobacco and ragweed and the other two were completely negative. Of the ten who gave immediate reactions, five had reagins to tobacco on passive transfer. Eosinophils, varying in numbers, were found in the histologic sections of the immediate urticarial wheals produced by the tobacco allergen in six of eight cases of thrombo-angiitis obliterans and in one case of migrating phlebitis. The biopsies of two patients with thrombo-angiitis obliterans and one with coronary artery thrombosis, in whom delayed reactions developed, showed an acute dermatitis. The exciting role of tobacco in the twelve patients observed was corroborated clinically by arrest in the progress of symptoms when the use of tobacco was discontinued. In one patient giving a delayed eczematous type of local reaction, a generalized eczema and exacerbation of the symptoms of thrombo-angiitis obliterans were induced by repeated subcutaneous injections of tobacco extract.

Phenylpropanolamine Hydrochloride in Allergy.—The propadrine that Boyer used in the treatment of forty-four instances of allergic conditions (asthma, urticaria and pollen asthma) was the hydrochloride of the racemic *dl*-form, melting point from 190 to 191 C. The salt is readily soluble in water, and aqueous solutions appear to be stable over long periods. Propadrine hydrochloride was used freely. As much as 0.05 Gm. was administered every two hours for five days or more without any toxic manifestations. Previously, the patients had been taking ephedrine or other drugs for the control of their symptoms. Four patients stated that propadrine hydrochloride was inferior to other forms of medication (usually ephedrine), five believed propadrine hydrochloride to be equally efficacious to previous medication and thirty-five patients reported that their greatest symptomatic improvement occurred with propadrine hydrochloride. Clinically, bronchial spasm, rhinitis and sneezing were relieved. There were no side reactions, so commonly encountered in the administration of ephedrine. In a large number of cases the patients derived marked relief without the usual manifestations of nervousness and insomnia, a frequent complaint of patients when using ephedrine. It is not necessary to administer sedatives with propadrine hydrochloride. It appears that propadrine hydrochloride may be used safely in

cases of hypertrophy of the prostate. Tachycardia and palpitation, which have been fairly common symptoms associated with the administration of ephedrine, were not encountered in the present patients.

Healing of Fractures of Atrophic Bones.—Goisman and Compere endeavored to determine whether or not the fractures of atrophic bones unite at the same rate and to the same extent as fractures of normal bones of patients of similar ages. Ten cases of fracture and seventy-seven cases of osteotomy of atrophic long bones were studied. Too many variables were present to make possible a satisfactory scientific comparison or analysis; the impression gained was that union occurred as readily in fractures of atrophic bones as in fractures of bones of normal density. The osteotomies also healed promptly. In experiments, instead of attempting to produce regional atrophy by paralysis or immobilization, the authors attempted to bring about generalized wasting of bones both in adult and in young growing rats by reducing the intake of calcium. The rate and degree of fracture healing in these animals was compared with others on a normal stock diet or on a diet with excessive amounts of cod liver oil or calcium, or both. The observation of Clarke, Bassin and Smith that it is possible to produce atrophy of the bones of young growing rats by feeding a diet which is deficient in calcium, without the development of rickets, was confirmed. The changes in the skeleton caused by diets deficient in minerals are quite similar (although generalized) to the local atrophy of bone resulting from disuse, produced experimentally by Allison and Brooks. The addition of ammonium nitrate to the low calcium diet of adult rats failed to produce demonstrable atrophy. All fractures in adult rats in all the groups appeared to heal equally well. Definite roentgenographic and microscopic evidence of bone atrophy was obtained in the growing rats fed on a low mineral diet. Fractures of nonrachitic atrophic bone in clinical and experimental cases united as rapidly as did fractures in the normal controls, from which one may conclude that mesodermal tissue cells proliferate as well in the repair of a thin bone matrix as in that of a bone matrix of normal density, and perhaps sometimes more easily in the former. Fractures of bones in either young or old rats on diets deficient in mineral did not heal more promptly or more adequately when large amounts of vitamin D or calcium, or of both substances, were added to the diets than did those in rats which had been on a normal basic diet previous to fracture; in some instances these

supplements seemed to retard the repair of bone. Atrophy of the fractured bone, both in the low calcium group and in the group of rats on the stock diet, was consistently more marked than in the unfractured extremity of the same animals. This may be explained by the fact that for a period of about two weeks after fracture the limb was not used normally. The studies would seem to indicate that there is a normal mineral and vitamin threshold below which bones become atrophic. If the deficiency of vitamin D is marked, rickets also develops and fractures of the rachitic bones heal poorly. If the deficiency is largely of the mineral element, bones may become atrophic with no rachitic changes without affecting the rate of fracture healing, and the quality of union will be comparable to the quality of the bone fractured.

Sacro-Iliac Strains.—Haldeman and Soto-Hall treated forty-two consecutive patients in whom the diagnosis of probable sacro-iliac strain had been made by manipulation and the injection of procaine hydrochloride into the sacro-iliac joint. In order to prevent any possible reaction from the procaine hydrochloride, the patient is placed in the prone position and 0.2 Gm. of sodium amytal is given orally. From 20 to 30 cc. of a 1 per cent solution of procaine hydrochloride is injected. In cases of bilateral sacro-iliac strain, 15 or 20 cc. of the solution may be injected into each side. The best approach to the sacro-iliac joint requires the insertion of a long (spinal puncture) needle at a point over the sacrum midway between the two posterior superior spines of the ilium. The needle is then directed toward the desired side so as to make an angle of 45 degrees with the skin. At this angle the needle will pass between the lateral portion of the sacrum and the overhanging posterior superior iliac spine, through the fibers of the interosseous sacro-iliac ligament to the posterior margin of the sacro-iliac joint. The procaine hydrochloride is injected slowly while the needle is being inserted. After bony resistance is encountered, the needle is partially withdrawn and reinserted several times, so as to obtain a fan-shaped area of infiltration along the posterior aspect of the sacro-iliac joint. The needle should not be inserted at such an angle that it will pass superior to the upper margin of the sacrum. After five or ten minutes in which time local anesthesia takes place, manipulation of the sacro-iliac joints is carried out. Such manipulations include straight-leg raising, hyperextension of the hip with the knee flexed and the patient in the prone position, sudden traction on one leg while the other is fixed, and the method whereby with the patient in the supine position one shoulder is pressed against the table and the pelvis on the same side is rotated forward as far as possible. The lower part of the back is then strapped with adhesive tape and the patient reports back in a few days. In a few cases exacerbation of sciatic pain for a day or two following the manipulation required an analgesic. In a few instances in which relief was transitory the injection of procaine was repeated after one week, usually with additional improvement. The injection caused an immediate transient disappearance of signs and symptoms in most of the cases, and in 60 per cent the relief obtained was more lasting. This procedure affords a method of determining whether a disorder of the sacro-iliac joint is responsible for the patient's symptoms.

Hookworm Survey of CCC Enrollees.—Cornell states that, of 1,079 CCC enrollees from the South, 597 (55.3 per cent) were found infested with hookworm. Following treatment, three successive specimens were found negative in 99.39 per cent of the 489 men examined. Samples of feces and soil beneath them, which had lain outdoors for several months in New York state, were found negative for hookworm ova and larvae. In the future it is believed that such a survey should be conducted by an independent laboratory group, working at successive collecting points throughout the area. This would speed up the survey so that fewer men would be discharged before treatment is given.

Progress in Gastro-Enterology in 1936 and 1937. E. S. Emery Jr., Boston.—p. 42.

Placental Transfer of Sulfanilamide.—In order to determine the placental transfer of sulfanilamide, Barker analyzed samples of maternal venous blood (from seventeen pregnant women suffering from infectious diseases who had received the drug shortly before delivery) and of umbilical vein blood for free sulfanilamide content, according to the method of Marshall. He found that sulfanilamide given orally to the mother in labor is found in almost equal concentrations in maternal and fetal venous bloods. Apparently the placenta is freely permeable to the drug, and fetal complications from excessive maternal dosage are theoretically possible. No complications occurred in any of the infants of this group. The doses administered, however, were small in comparison with those that would be necessary in the treatment of severe maternal infections.

Renal Tuberculosis.—Lieberthal made a combined clinical and pathologic investigation of 270 cases of renal tuberculosis. In addition, postmortem studies and animal experiments were carried out to clear up certain problems which were not explained by clinical examination of the clinical cases. 1. The kidney shows a peculiar immunity to tuberculous infection by virtue of its rich blood supply and the large caliber of its capillaries. Hematogenic tuberculous infection of that organ becomes possible through the medium of embolism. 2. The initial lesions are situated mainly in the cortex and are usually bilateral. 3. In the spread of the tuberculous lesion through the kidney, three definite stages are evident: metastatic tubercles appear in the renal substance, a caseous ulcer appears on a renal papilla and a descending infection of the urinary mucous membranes follows and then an ascending reinfection of the previously uninvolved portions of the renal tissue occurs. 4. In this ascending reinfection of the renal tissue, the arterial system of the kidney plays a leading part. 5. Tuberculous strictures of the ureter and of individual calices lead to a stasis of tuberculous urine, which has a leading part in the maintenance and spread of the tuberculous process through the kidney. 6. This stasis also gives rise to hydronephrotic changes, which go hand in hand with tuberculous erosion to cause destruction of renal tissue. 7. Tuberculous lesions in the kidney have a tendency to heal, but as soon as the process breaks into and communicates with the lumen of the renal pelvis peculiar conditions are produced which counteract the tendency to heal. 8. Tuberculous lesions in the first stage are latent and cannot be diagnosed clinically. 9. Secondary nontuberculous changes which alter the final pathologic picture may occur in cases of renal tuberculosis.

Renal Tuberculosis in Pulmonary Tuberculosis.—Jameson declares that careful and repeated search for acid fast bacilli in smears of the sediment of a twenty-four hour specimen of urine should be made in every tuberculous patient who shows pus or albumin in the urine. Such smears, properly stained, will show acid fast organisms in a high percentage (28.4 per cent of 239 patients dying of active pulmonary tuberculosis) of positive cases. Doubtful cases and all those in which acid fast bacilli have been demonstrated should be further examined by guinea pig inoculation or culture. Renal tuberculosis was found to be three times as frequent in men as it is in women with pulmonary tuberculosis in this series, and in 76 per cent of these patients the lesions are bilateral. Patients with renal tuberculosis rarely have a "normal" urine, although the presence of tubercle bacilluria depends on the existence of a lesion in communication with the pelvis of the kidney.

Hemorrhage from Carcinoma of Cervix.—Leventhal and his associates performed bilateral extraperitoneal ligation of the hypogastric arteries in five cases for severe hemorrhage following maximal radiation therapy for carcinoma of the cervix. A few minor complications were experienced during the operative procedure in several instances. In one case the internal iliac vein was punctured and had to be ligated; in two cases metastatic glands were encountered along the large vessels, but these could be easily displaced to permit exposure of the hypogastric artery. No harmful changes occur in the bladder or rectum following ligation of the extraperitoneal hypogastric artery, because of the collateral circulation. This simple operation is followed by no primary mortality and is of value as a palliative measure or as the only procedure for uncontrollable hemorrhage from cervical carcinoma.

Yeastlike Fungi of the Human Vagina.—Weinstein and Wickerham estimated the incidence of the yeastlike fungi in the vaginal secretions of 375 women who were normal or pregnant or had some disease of the female genitalia. In addition to a study of the incidence of the yeastlike organisms, cultural determinations of the remainder of the bacterial flora of the vagina were made in each case, so that the complete bacteriologic picture was obtained. It was found that 23.3 per cent of the pregnant and 7.3 per cent of nonpregnant women harbored yeastlike organisms; that is, 64 per cent of the nonpregnant group and 56 per cent of the pregnant showed signs of infection of the vagina by these organisms. The absence of disease of the vagina when yeastlike fungi are present is not necessarily an indication of the nonpathogenicity of the organism but may indicate a resistance on the part of the host. There seems to be strong evidence for the existence of a carrier state with the yeastlike fungi. *Monilia albicans* was isolated thirty-five times, *Torula* nine, *Saccharomyces* four, *Monilia parapsilosis* twice and *Mycoderma* once. The identity of these organisms was established on the basis of cultural and fermentation reactions. Studies of the vaginal flora in cases in which yeastlike fungi were present revealed that the *Döderlein* bacillus can be recovered with great frequency, thus casting doubt on the inference that this organism is an indicator of vaginal health. *Staphylococcus aureus* (seven) and *albus* (thirty-three), hemolytic (eight) and nonhemolytic (eighteen) streptococci and *Escherichia coli* (four) were also recovered.

*Seasonal Incidence of Rheumatic Fever in This Country. A. B. Rowlands.—p. 15.

Infiltration of Stellate Ganglion for Apoplexy.—Mackey and Scott carried out infiltration of the region of the stellate ganglion on nineteen cases of apoplexy; a definite clinical improvement followed nine of these injections. Only in one case—the youngest patient of the series—was the improvement dramatic, and in this instance the immediate beneficial effect of the treatment cannot be doubted. In the other cases the degree of improvement was relatively slight. In one instance the injection was followed by respiratory failure, apparently produced by the solution being accidentally introduced into a vein. The results obtained do not justify the adoption of anesthesia of the stellate ganglion as a routine method of treatment in apoplexy, but further study is necessary before the method can be rejected as of negligible value. The use of the method in cases of severe cerebral hemorrhage in patients of middle age and older will serve only to bring it into disrepute. Cases of cerebral thrombosis may show some improvement of the clinical condition following anesthesia of the stellate ganglion; the degree of such improvement will be partly dependent on how much arterial sclerosis is present. The ideal case would seem to be one of cerebral embolism, especially in the young. The treatment should be given as soon after the onset of the apoplexy as possible. Only a negligible degree of improvement can be expected if the illness has lasted longer than twenty-four hours before treatment is instituted.

Seasonal Incidence of Rheumatic Fever.—Rowlands shows by a graph the onset of symptoms in nearly 1,500 first attacks of rheumatic fever (St. Bartholomew's Hospital, from 1882 to 1904), from the study of which there can be no doubt that in England there is a significant correlation between the seasonal variations of rheumatic fever and the rates of change of temperature and relative humidity. There are two well established associations between climate and the incidence of rheumatic fever: 1. Newsholme (1935) has clearly demonstrated that the incidence of rheumatic fever is highest in hot dry years. 2. Damp cold has been implicated by numerous workers (Poynton and Schlesinger, 1937). At first glance these associations appear to be mutually antagonistic. Fortunately this paradox is apparent rather than real. The maximal seasonal incidence of rheumatic fever does not occur in the hottest and driest months; neither does it occur in the damp cold of winter. It is to be found between the two, when the hot dry conditions of summer are changing most rapidly to the damp cold of winter. While hot dry conditions predispose to the onset of rheumatic fever, it is the rate of change to damp cold which acts as the precipitating climatic factor.

*Para-Aminobenzene Sulfonamide in Treatment of Pyelitis of Pregnancy. A. Barr.—p. 18.

Sulfanilamide in Pyelitis of Pregnancy.—Barr treated sixty-four cases of pyelitis of pregnancy with sulfanilamide. Simple cases can be cured in from four to five days with sulfanilamide. Renal and toxic pyelitis requires a larger dosage of the drug and a longer time (fourteen days) to sterilize the urine. The treatment is more quickly effective than any other standard line of treatment for pyelitis in pregnancy, and now it should seldom be necessary to resort to ureteral drainage or termination of pregnancy in these cases. The immediate improvement in the general appearance of the patient and her obvious feeling of well being shortly after the treatment is

begun is in marked contrast to the depression of patients taking large quantities of alkalis. Catheterization of the ureters has been unnecessary in this series even in cases of the gross toxicity. Induction of premature labor was not necessary and all patients with the exception of the two in whom miscarriages occurred went to term. In slight pyelitis from 0.5 to 0.6 Gm. of sulfanilamide three times a day rapidly produced a remission of symptoms—usually within forty-eight hours. In the severe cases a dosage of from 1.8 to 2.4 Gm. a day was required to sterilize the urine in an average of fourteen days. In the toxic cases in which nausea and vomiting were prominent features, oral administration of the drug was impossible and daily injections of prontosil (Winthrop) were given in 10 cc. doses, and in from four to five days administration of the drug by mouth was usually possible. Administration of prontosil did not seem so effective and in from five to seven days, although there was a slow improvement in the general condition of the patients, there was no material change in the bacterial content of the urine. As soon as the administration of sulfanilamide by mouth was begun there was a rapid change in the general condition, and the urine was sterile in an average of fourteen days as in the renal cases, with the same dosage.

Induction of Labor by Puncture of Membranes: Review of 357 Cases. R. A. Tennent.—p. 509.

Etiology of Thrombosis and Embolism.—Dougal contends that tissue trauma and sepsis are the two primary causative factors of thrombosis and embolism and that as they frequently coexist in cases of thrombosis it is difficult to decide which is the more important. Slowing of the circulation is so important a predisposing cause of thrombosis that it is almost a sine qua non. There are certain contributory factors. The main problem in etiology is to find why intravascular clotting is liable to occur after labor or a surgical operation. The author is of the opinion that a subtotal hysterectomy is more liable to be followed by thrombosis than a total hysterectomy, and he believes the reason to be that in the latter operation a small opening is left for drainage at the upper end of the vagina. If there is no drainage a certain amount of blood or tissue juice may be retained and serve either as a source of thrombokinase or other coagulant or as a nidus for the growth of low grade micro-organisms. He believes the second possibility to be the more likely one. The most important secondary factor is venous stasis, and its presence is usually necessary because thrombosis rarely occurs if the blood flows freely. The blood changes are also important but only to the extent that they cause the blood to coagulate more readily or more efficiently. As these changes are fairly constant in puerperal and postoperative cases, it means that these patients are more susceptible than others to the dangers of intravascular clotting. Injury to the wall of the vessel would be a primary factor if it could be shown that postoperative thrombosis has its origin in ligated, clamped or otherwise injured vessels in the course of surgical intervention, but until this has been demonstrated it must be regarded as a secondary factor linked up with trauma to tissue and sepsis.

Postoperative Exercises as Preventive of Embolism.—By comparing the incidence of postoperative embolism (in two institutions, in wards under the care of the same gynecologist, admitting the same type of patient, with the same preoperative and postoperative treatment—except that in only one institution systematic graduated postoperative exercises were given) Shaw and Rickards assess the value of postoperative exercises as a preventive of embolism. In the hospital in which graduated exercises were performed the incidence of fatal pulmonary embolism was 0.06 per cent in 1,635 consecutive operations. In the other hospital, without graduated

exercises, the same gynecologist in the same twelve years performed 3,618 operations with an incidence of fatal pulmonary embolism of 0.304 per cent, a percentage incidence five times as great as in the other group. The exercises carried out were as follows: The convalescent patients lift their arms high over their heads twenty times and then, lying on their backs, lift each leg the same number of times. During the first few days after an operation the patients cannot elevate their limbs so often but, even a day after an operation, the patient can lift her arms a few times while her legs can be drawn up to her body and then fully extended. This necessitates the removal of the pillow which normally supports her legs, and this is probably one of the greatest benefits, as the constant clinging pressure on the back of the thighs must retard the venous circulation.

Treatment of Puerperal Sepsis by Prontosil.—Brown used prontosil (Winthrop) in the treatment of thirty-nine cases of puerperal sepsis due to the hemolytic streptococcus (group A of Lancefield) and in the treatment of thirty-five cases of mastitis and eight cases of *Bacillus coli* infection of the urinary tract. Of the thirty-nine patients suffering from puerperal sepsis there were twenty-seven with local infection of the uterus, eight with septicemia (two of whom also had general peritonitis) and four cases of general peritonitis alone. Prontosil was administered intramuscularly and by mouth. Prontosil soluble was used in all the cases of puerperal sepsis, but in four mild cases the dosage was not more than 1 Gm. In the first five cases treated the first dose was given intravenously but in the remainder of the cases by intramuscular injection. It was given in the dosage of 20 cc. (0.5 Gm.) two or three times daily, the amount being decreased as the patient improved. There was marked improvement in eleven of the twenty-seven patients with local infection of the uterus after the administration of prontosil; in one patient it had no effect and in one death occurred from agranulocytosis after the sepsis had apparently been controlled. These patients were seriously ill. In the eleven successfully treated cases the average total dosage of prontosil was 42.6 Gm. The fourteen other cases were of mild or moderate severity and recovery would almost certainly have occurred without prontosil. Of the eight patients with proved septicemia six recovered—a mortality of 25 per cent. One of these patients who died was the first to be treated with prontosil and the dosage was inadequate. The second fatal case was admitted four days after a manual removal of the placenta. Of the four patients with general peritonitis not associated with a septicemia, all recovered. Relapses occurred in three of the patients but responded when the drug was readministered. The thirty-five patients with mastitis have been treated by the administration of sulfanilamide, benzyl aminobenzene sulfonamide or sulfonamide-P (sulfanilamide) in the dosage of from 2 to 3 Gm. daily. The average duration of treatment was five days. All were severe cases and a few of the patients were extremely ill. The mastitis resolved completely and patients in whom mastitis developed in the hospital have not had any abscesses of the breast, that is, since prontosil was used for acute mastitis. The author has also used sulfanilamide in the treatment of a number of patients admitted for abscesses of the breast and although most of these have required incision they have all appeared to heal more rapidly than usual.

- *Therapeutic Effect of Vitamin P in Schönlein-Henoch Purpura. T. Jersild.—p. 1445.

Strawberry Nevus.—From a review of the literature and study of seventy-seven cases (ninety-three nevi) of nevi it appears to Lister that strawberry nevi of infants have a natural history entirely different from that of any other type. The essential point of distinction is that they grow more or less

rapidly during the first few months after their appearance. This never continues for more than a year, and commonly it ceases between the sixth and eighth months. Thereafter retrogression sets in. Usually all trace of color has been obliterated by the fifth year, if not earlier, and only the most prominent nevi require more time for the final absorption of the redundant skin. This is the explanation of the uniformly good results recorded by surgeons, whatever the method. Those nevi which develop into large vascular tumors in adults have an entirely different early history. The treatment of strawberry nevi must be based on the knowledge of their invariable tendency to spontaneous retrogression. If the nevus cannot be quickly and safely obliterated, the mother should be reassured that however distressing the disfigurement may now appear it will inevitably fade. The object in advocating expectant treatment is to ensure that ultimately no unsightly or disabling scar will be left. There is more cause for anxiety if a nevus shows no active growth in infancy, for it is then unlikely to retrogress of its own accord.

Vitamin P in Schönlein-Henoch Purpura.—Jersild cites a case of Schönlein-Henoch purpura in which all the characteristic symptoms were promptly influenced by treatment with vitamin P. During the past eight years the patient presented several of the characteristic features of Schönlein-Henoch purpura (vomiting, colic, constipation, occasional blood-stained discharges, purpura, urticaria, transient edema, pain and swelling of joints, renal colic, albuminuria and hematuria). When the capillary resistance was tested by Göthlin's method the patient showed fifty petechiae, which denotes increased permeability of the capillaries. The same result was obtained by suction. There is generally held to be a direct relationship between low capillary resistance and deficiency of vitamin C. Accordingly the effect of ascorbic acid was tested before treatment with vitamin P was begun, and 300 mg. of ascorbic acid was injected intravenously every day for a week. The results were negative. The capillary resistance remained unchanged and fresh ecchymoses appeared spontaneously. Vitamin P was then given in the form of daily intravenous injections of 50 mg. of citrin. During treatment with citrin the capillary resistance rose and the ecchymoses disappeared. When the injection of citrin was stopped the capillary resistance fell and new ecchymoses appeared. When citrin was again given the capillary resistance increased again and the ecchymoses faded. During treatment with citrin the patient lost all symptoms of Schönlein-Henoch purpura. The symptoms characteristic of Schönlein-Henoch purpura may be explained as being the result of an abnormal capillary resistance, and this theory is supported by the observations of Müller (1922), who found dilated, elongated and twisted capillaries in the skin of cases of Schönlein-Henoch purpura. The effect of vitamin P is to regulate the permeability of capillaries and it was undoubtedly this effect which was responsible for the good progress in the author's patient. Thus it seems that one is justified in assuming that Schönlein-Henoch purpura is caused by deficiency of vitamin P.

Neonatal Jaundice.—Kawakami and Yogo treated three cases of severe neonatal jaundice by inserting a catheter into the stomach of the newborn infant and administering through it a preparation of magnesium sulfate and hydrochloric acid: from 2 to 3 cc. of a mixture of 10 Gm. of magnesium sulfate, 1 cc. of dilute hydrochloric acid and 90 cc. of water with from 20 to 30 cc. of mother's milk. This is done three or four times a day at intervals of several hours. The treatment proved efficacious as in from one to three days the jaundice disappeared, the appetite returned to normal and the temperature fell to normal.

Hereditary Hyperbilirubinemia.—Tecon believes that it is possible and necessary to differentiate between familial cholemia and hereditary hemolytic icterus. The criteria which he regards as valid are not the clinical symptoms, which may be identical, or the hematologic signs or the biochemical aspects, because the microspherocytosis is not constant and it is observed in related conditions; nor is it either the quality or the degree of bilirubinemia. The only conception which is sufficiently comprehensive to take account of all the facts is the biologic idea of the development of the disease in question in an individual, together with his ancestry and descendants. When studying the families of patients with hemolytic icterus and of those with hereditary cholemia in the light of this criterion, it is difficult for one not to conclude that the two types of disorders are closely related but different in their biologic manifestations. This differentiation seems to correspond to the observed facts. The author stresses the following points: 1. Familial cholemia is an independent disturbance, which is hereditary and congenital and which is transmitted according to the laws of heredity with dominant character; it must be clearly differentiated from hereditary hemolytic icterus; it belongs to the group of familial and hereditary hepatoses. 2. Familial chronic hemolytic icterus is a distinct disease, which is congenital and which is transmitted by both sexes according to the laws of heredity with dominant character; it is distinctly different from familial cholemia. 3. The differential diagnosis is easy in the typical cases, but it is so difficult in the atypical cases that it cannot be established with certainty before the patient has been observed for some time, has been subjected to repeated examinations and has had his family history investigated. Moreover, the diagnosis is reliable only if made by a physician who is thoroughly familiar with both disorders. The prognosis and therapy of the two disorders are so different that great efforts should be made to make a precise differential diagnosis.

Cardiac Insufficiency After Delivery.—Broustet and Mahon point out that the view that delivery marks the end of a dangerous period for cardiac patients is not true of all cases. In a certain number of patients the cardiac insufficiency, which was already manifest during gestation, continues during the puerperal period. There are even women with cardiopathy who passed through pregnancy and delivery without accident and in whom severe circulatory accidents developed during the postpartal period. The author believes that among women with cardiopathy the incidence of postpartum cardiac insufficiency is approximately 16 per cent. Of ten women with mitral cardiopathy who arrive at the end of their gestation, one or two are likely to develop manifestations of cardiac insufficiency after delivery. This cardiac insufficiency takes the form of a progressive asystole or of an acute pulmonary edema. The author thinks that these cardiac insufficiencies are essentially the result of the reentry into the general circulation of the masses of blood that accumulated after delivery in the venous depots of the abdomen. This encumbrance of the circulation in turn elicits a crisis of acute edema in the

patients with well compensated mitral cardiopathies, in whom until then the auricle was hypertrophied but not dilated. In others, in whom the auricle was already deficient and the pulmonary circulation overloaded, it produces a progressive augmentation of the pulmonary stasis, which often advances inexorably. The evolution of this form involves great danger, especially if it is accompanied by fever. The immediate and ultimate prognosis of acute edema is much more favorable. The fact that the woman is in the puerperal stage does not alter the classic treatment of these diverse manifestations of cardiac insufficiency.

*Nonpulmonary Form of Hemoptysis: Tracheal Hemorrhages (Hemorrhagic Tracheitis). V. Cordier and P. L. Mounier-Kuhn.—p. 1065.

Postserotherapeutic Radial Paralysis. C. Angelesco, A. N. Popovici and I. Balutza.—p. 1068.

Tracheal Hemorrhages.—Cordier and Mounier-Kuhn reserve the term tracheal hemorrhages for repeated hemoptyses, the tracheal origin of which is verified by endoscopy and in a less distinct manner by indirect tracheostomy. The authors say that the patients may request medical aid at the time of their first hemoptysis or because, although apparently in good health, they have had blood in the sputum for some time. Systematic bronchoscopy and clinical examination may suggest the possibility of a tracheal hemorrhage. The hemoptyses differ; a mouthful of blood may be expelled after a sudden effort, but in the majority of cases the expulsive cough is absent. In this respect the condition differs from tuberculous hemoptysis, in which the expulsive cough is rarely absent. The expectoration without effort (but with retrosternal tingling) impresses and reassures the patient; in drawing the physician's attention to this, he puts him on guard against an overhasty diagnosis of tuberculous hemoptysis. A definite diagnosis should never be made without a tracheoscopy, which may reveal (1) individualized lesions, such as malignant or benign tumors or, in exceptional cases, syphilitic or tuberculous lesions, (2) autochthonous tracheal lesions, which are diffuse, indicating sanguineous dyscrasias (tracheal purpura, angeitis of Osler and so on) and (3) a hemorrhagic tracheitis with fixed topography, probably in relation to a tuberculous adenomediastinitis; these tuberculous lesions are old but the hemorrhagic tracheitis, although it may make careful observation necessary, does not have to be treated like a developing tuberculous process. Besides these cases there exists still another form of tracheal hemorrhage for which no explanation has been found as yet. The author says that treatment is of little avail. Local application of cocaine-epinephrine or of silver nitrate have an ephemeral effect in most cases. Inhalation of antiseptic vapors or similar measures are ineffective. The employment of coagulants is beneficial; if a spirochetosis exists, acetarsone is often efficacious. In angiomatous tumefactions, cauterization gives temporary improvement. However, the diagnosis of the disease is generally more important than is the cure, as was indicated by observations on several patients whose lives had been spoiled by worries about these repeated hemorrhages.

Male Hormones in Hypertrophy of Prostate.—Champy and his associates point out that a connection between the hypertrophy of the prostate and disturbances in the internal secretion of the testes has been suggested for a long time. They cite authors who observed regression of the prostatic hypertrophy after castration and they also direct attention to the effect of the suppression of the external secretion by means of ligation of the deferent ducts. On the other hand, it has been suggested that the internal testicular secretion be stimulated rather than the external secretion suppressed. The authors show that it is not illogical that the one as well as the other method will produce results. They cite animal experiments as well as clinical observations and explain the action of the sex hormones on the

prostate and the action of Steinach's operation. From the practical point of view they give preference to the treatment with purified testicular lipoids, because these show themselves more active on the perivascular edema of the prostate than their equivalent of testosterone. Moreover, the purified testicular lipoids are easily administered by the digestive tract. This mode of administration permits the distribution of the doses. The latter factor appears essential to the authors in that the hormones are not entirely harmless. In order to produce a reaction in the genital glands, it is not necessary to give large quantities of hormone every day. The injection produces "peaks" in the hormone content of the blood, which may be useful at the time of an attack, but the authors regard it as imprudent to prolong this condition. The treatment must be continuous, as in the case of insulin therapy, but in strictly sufficient doses. Endocrine therapy can be useful also as an adjuvant to the endoscopic resection of the hypertrophied prostate, in that it will make the effects of this surgical treatment more lasting. The authors say that one of them recommended the combination of surgical and endocrine treatment as early as 1930. As the endoscopic operation cannot entirely destroy the adenoma, they think that it is advisable to try to arrest the growth of the adenoma and to restore to the smooth muscle the extensibility it has during youth.

Action Mechanism of Female Sex Hormones. F. Kovács.—p. 93.

Vitamin C Tolerance During Menstrual Cycle.—In the first part of this paper Winkler and Seebach evaluate the different methods that have been recommended for the determination of ascorbic acid. Further, they studied the curve of elimination in case of oral and of parenteral administration. They found that in case of intravenous administration the maximum of the elimination is reached in from sixty to ninety minutes after the injection; the curve remains at this level for about one hour and after that decreases suddenly. In case of intramuscular injection, the maximum is reached less suddenly; the curve has two peaks (after one and a half and three and a half hours). This curve indicates that the depot produced by intramuscular injection is slowly evacuated. In case of oral administration, the curve rises in a straight line until the maximum is reached in about three and a half hours, but one hour later it already has declined again. In the second part of their report, the authors discuss ascorbic acid tolerance tests during the menstrual cycle. In tolerance tests on twelve women they were unable to find a relation between the menstrual cycle and the ascorbic acid elimination in the urine. In eight of the women examined, disturbances in the general condition resulted, such as headaches, lack of appetite, vertigo, fatigue, depression and reduced capacity of association. The headaches usually appeared two or three hours after oral administration. The fact that the disturbances appear on the second or fourth day of the tolerance test, that is, at a time when the organism is not yet saturated with the vitamin, indicates that hypervitaminosis cannot be the cause of the disturbances. The freedom from disorders in case of the parenteral intake of the vitamin and their severity in case of oral administration suggest that the mode of absorption is an important factor in their development. The authors suggest that the administration of sodium bicarbonate will help in preventing the disorders without interfering with the absorption of the vitamin.

Chyle Angiectasia and Cystic Lympho-Angio-Endothelioma of Mesentery. E. Fiorini.—p. 758.

Appendicular Mesenteriolitis.—Beluffi made microscopic studies of 245 appendixes and their mesenteries which were surgically removed for various forms of chronic or acute appendicitis. He concludes that the appendicular mesentery shows

microscopic lesions which vary with the form of appendicitis and are proportional to the intensity of the disease. In acute appendicitis the mesentery shows edema, exudation, cellular infiltration, lymphangitis, rapid mobilization of reticulo-endothelial cells and perivascular infiltration. In grave cases, alterations of the local circulation take place and may be complicated by venous thrombosis and, in rare cases, by suppurative thrombophlebitis or liver abscess. After regression of acute appendicitis the appendicular mesentery shows structural changes such as retraction, formation of adhesions, thickness of the connective tissue and of the vascular walls and also the presence of lymphatic infiltration. The structural changes of the mesentery after acute appendicitis are permanent. Their presence allows a retrospective diagnosis of acute appendicitis. The structural changes of the mesentery induce mechanical and functional disorders of the appendix by which secretory stasis and the development of further attacks of acute appendicitis are stimulated. It seems possible that the infection may be transmitted through the mesentery to distant abdominal viscera even after appendectomy, which fact shows the advisability of performing an ample removal of mesentery during appendectomy followed by peritonealization of the cut surfaces of the structure.

*Ketone Bodies in Blood and in Urine in Decompensated Heart Diseases. L. Capani.—p. 304.
Malformation of Heart and Congenital Complete Atrioventricular Dissociation: Case. A. Calò.—p. 323.

Ketone Bodies in Heart Diseases.—Capani studied the behavior of the ketone bodies in the blood and urine of fourteen patients suffering from heart diseases in different phases of decompensation. He found that ketonemia is almost normal in decompensated heart diseases without edema and increased in the presence of edema. Ketonemia parallels the intensity of edema and diminishes with improvement of the circulatory conditions. The highest levels of ketonemia are observed in the blood of patients who are in the preterminal phase of decompensated heart disease with anasarca. There is no relation between ketosuria and ketonemia. Ketosis in decompensated heart diseases with edema depends on the diminished velocity of the circulation, which results in a diminished ketolysis at the tissues and disorders in the interchange between the blood and the interstitial fluids with consequent accumulation of ketone in both fluids.

Venous Pressure During Occlusion of Femoral Artery.—Chiorazzo and Perini induced occlusion of the femoral artery in thirty cases by means of the application of an elastic bandage at the thigh (Cardarelli-Katzenstein test). They found that the test in normal persons induces transient tachycardia, which is followed by bradycardia, increased systolic pressure in the arteries and diminution of the venous pressure. This circulatory phenomenon disappears immediately after removal of the elastic occluding bandage. The greatest arterial pressure may or may not be increased in the course of the test in persons who do not have heart disease but a hypotonic heart. In all cases, however, the venous pressure diminishes during the test. In heart diseases with actual or latent decompensation the test induces tachycardia, lowering of the greatest arterial pressure and increase of the venous pressure. In actual or latent insufficiency of the left side of the heart the arterial and venous pressure diminishes during the test. Patients who are suffering from heart disease and react as do normal persons during the test are considered as having lasting compensation. According to the authors the test shows myocardial insufficiency early in the evolution of the disease, at a time at which the clinical symptoms of decompensation have not yet appeared. Several types of heart insufficiency can be differentiated by the behavior of the venous pressure in the course of the test.

Renal Cancer.—Torre observed the elimination of urea, indigo carmine and phenolsulfonphthalein in the separated urine of both kidneys of eleven patients suffering from unilateral renal cancer. He found that the urea was eliminated at the same speed and concentration by the normal as by the cancerous kidney in nine cases, whereas it was delayed and insufficient in two. The elimination of indigo carmine was also the same for the two kidneys in nine cases whereas it was diminished in two. The phenolsulfonphthalein test gave the same results for the two kidneys in seven cases. In four the elimination of phenolsulfonphthalein by the cancerous kidney was insufficient and the normal kidney was in vicarious hyperfunction. The microscopic study of the renal parenchyma showed that the portion which was not infiltrated by cancer was normal in nine cases. It was the seat of sclerosis in one case and of suppuration in another case. In both cases the tests of elimination of urea and color substances gave results showing deficiency. The author concludes that the results of chromoscopy and of the tests of elimination of urea and phenolsulfonphthalein may be erroneous, showing normal function of the cancerous kidney even in advanced phases of the condition if a certain part of the renal parenchyma is not involved by the tumor. The results of the tests show insufficiency of the structure if the renal parenchyma is the seat of lesions other than involvement by the tumor. The false results of the tests in the presence of unilateral renal cancer depend on the preservation of the renal parenchyma and on a dysfunction of the metabolism of urea which takes place in the course of unilateral renal cancer, owing to a reflex hypofunctioning action of the cancerous kidney on the normal kidney.

*Studies on Origin and Significance of Strawberry Gallbladder. E. Fenster.—p. 641.

Lipoidosis of Gallbladder.—Ahlin states that lipoidosis of the gallbladder is a fairly frequent observation in the pathologic section of St. Erik's hospital, Stockholm, and that it is found in various diseases. The sex distribution is about equal. There is an increase in the frequency between the ages of 40 and 50 years for women, whereas in man the incidence is about equal for the various ages. The gallbladder lipoidosis is in no way related to inflammatory alterations in the gallbladder wall and does not lead per se to serious disturbances. General disturbances of lipid metabolism play a part in the production of gallbladder lipoidosis. The frequent occurrence of this condition in obese persons speaks for this. Local conditions which, however, are as yet not understood may furnish the explanation for the occurrence of the condition by retention of lipoids in the mucosa. With the exception of pure cholesterol stones, the concurrence of stones and lipoidosis of the gallbladder is rare. For this reason the author considers it improbable that lipoidosis must precede stone formation and that there is a direct relationship between the two. However, it would be impossible to deny the existence of common etiologic factors for the two processes. Lipoidosis of the gallbladder is apparently a reversible process capable of complete restitution to the normal. The author's studies do not support Bernhard's conclusion that patients with gallbladder lipoidosis are more predisposed to cancer than other patients.

Strawberry Gallbladder.—The concept "strawberry gallbladder" as an independent disease entity, according to Fenster, and the contradictory interpretation of it as an accompanying lesion in the presence of other gallbladder and liver diseases

is due to the fact that the pathologists recognize two varieties of strawberry gallbladder; namely, the one characterized by an ordinary network and the other characterized by the formation of polyps. There is considerable unanimity as to the clinical picture. The author stresses the frequency of pericholecystic adhesions and enlargement of the lymph nodes of the cystic duct as one of the causes of the slowing of the lymph current in the gallbladder area and its role in the so-called serous inflammation. On the basis of his own experiments, the author favors the idea of absorption of cholesterol rather than of secretion, while at the same time rejecting inflammation as the only cause of development of the strawberry gallbladder. The role of certain mechanical conditions such as gallbladder stasis and dyskinesia are admitted. Fenster considers the cholesterol esters found in the bile of such gallbladders as a product of secretion of the bile and feels that its occurrence, as well as that of the quinine-resisting liver lipase in the blood, is a proof of the existence of damage to the liver parenchyma. The presence of larger deposits up to the formation of small polyps and the frequent occurrence of mulberry stones point to the relationship between strawberry gallbladder and gallstone formation. The frequent involvement of the pancreas is regarded in the same light as the parenchymatous lesions of the liver as a proof that strawberry gallbladder is not a harmless condition of local significance but an independent disease entity. The author stresses diagnostic difficulties, particularly in differentiating the strawberry gallbladder from dyskinesia. He advocates operative removal of the strawberry gallbladder combined in certain cases with dilation of the sphincter of Oddi. He regards the operative intervention as causative therapy in that it frees the patient from pain, removes the dyskinesia as well as a disease link in the gallbladder-pancreas-spleen system, as well as prophylaxis against gallstone formation.

Role of Thyroid in Clinical Course of Rickets. W. Haase.—p. 64.

Gastric Secretion After Cholecystectomy.—Bernhard and Eck state that, in 160 patients who had had a previous cholecystectomy, the gastric symptoms most frequently associated with gallbladder disease were in some cases relieved, while in some the operation had initiated these gastric disturbances and in others had no influence on them of any kind. The authors prepared a Pavlov pouch on five dogs, determined its secretory status and in a subsequent operation removed the gallbladder and then made further determinations of the gastric secretion. They noted a diminution in acid secretion in three of the dogs, while in two there was no alteration. They did note, however, an alteration in the manner of the secretion of the gastric juice. The pepsin content of the juice was regularly lowered, and the peak of the pepsin and the acidity was arrived at after a considerably delayed period. They concluded from their animal experiments that the removal of the gallbladder alone did not account for the high degree of subacidity and anacidity in patients suffering from gallstone disease. They have further shown that the pancreas and the liver as well as the gastritis and injuries to the vagus have a part in these alterations. It appeared that the beneficial influence on gastric secretion, as the result of the removal of the gallbladder, was limited to a few clinical forms of gallbladder disease. The authors studied the effect of cholecystectomy, which had been performed not less than fifteen years previously, on the gastric complaints and tolerance to fat of 175 patients. They noted that cholecystectomy performed for catarrhal cholecystitis without stones or for chronic cholecystitis with stones did not influence gastric complaints particularly favorably. The results, on the other hand, in acute and subacute cholecystitis were strikingly good. The fat tolerance was frequently aggravated through a cholecystectomy in catarrhal cholecystitis but markedly improved in the other two forms. The statements of the earlier authors as to

the frequency of subacidity and anacidity after cholecystectomy are not accurate for the reason that the height of acid secretion in the stomach of men after the removal of the gallbladder is not infrequently delayed so that the ordinary evacuation of the stomach contents gives erroneously low values. The authors stress the advisability of administering hydrochloric acid and pepsin before meals to patients with subacidity or anacidity.

Neuritis Caused by Prophylactic Tetanus Serum.—Mészáros says that the neuritis caused by vaccination against tetanus is comparatively rare. However, a knowledge that it may occur is important in decisions on accident compensation, since the neuritis caused by the tetanus serum may persist after the cure of the accidental injury. The author reviews the literature on this problem and then describes a case of his own observation. The patient developed an urticaria-like exanthem eleven days after the prophylactic tetanus vaccination and then neuralgic pains in the right arm and weakness in the right deltoid muscle, in the anterior serratus, in the latissimus dorsi and in the infraspinatus. On the basis of the connection in time and of the typical localization in the region of the fifth and sixth cervical roots, the neuritic symptoms must be regarded as sequels of the protective vaccination against tetanus, the more so since no other cause of the paralysis was demonstrable. The course may be designated as favorable, since the condition of the patient improved in nine months to such an extent that the patient could take up his work again; but even after two years there still remained a slight impairment. The assertion of some physicians that the damage to the nerves could not have been caused by the tetanus injection, since it had been made under the skin of the chest, that is, at a site distant from the impaired nerve, is refuted by the fact that the tetanus serum with its antitoxin content does not exert its action at the site of injection but after resorption attacks distant nerves. This is proved also by three other cases cited by the author. He concludes that these rare complications offer no argument against the prophylactic use of tetanus serum. Complete cure is usually obtained in about two years.

Vitamin E and Lactation.—Gaedke and Bennholdt-Thomsen say that it is generally assumed that vitamin E, the anti-sterility factor, has a favorable effect on lactation. However, no objective scientific proofs have been furnished as yet that vitamin E does stimulate lactation. For this reason the authors decided to study the action of additions of vitamin E to the normal diet, of the lactating action of wetnurses and on the growth of their nurslings. Of six wetnurses, two served as controls and were given only inactive substances. It was found that the quantity as well as the fat content of the milk remained uninfluenced by the addition of vitamin E to the normal diet. The infants being nursed by the wetnurses receiving the addition of vitamin E showed no essential difference in their increase in weight from the other two nurslings. The rates of growth in length likewise showed no deviations. All fluctuations were within the limits of the physiologic norm. Neither the wet-

nurses nor their children showed differences in their subjective conditions which could be ascribed to vitamin E. Moreover, the hemoglobin content of the blood of mothers and children remained uninfluenced by the fertility vitamin. The authors further describe animal experiments on vitamin E. They found that four of a litter of eight young rabbits which were given vitamin E in oil once a week showed retardation in their growth in comparison to the four other animals, which were given the same quantity of inactive olive oil. Three of the four animals which had undergone treatment with vitamin E died later as the result of the administration of massive doses of vitamin E, whereas only one of the four controls died. Studies on animals of another litter indicated that these unfavorable effects of vitamin E on rabbits were not the result of a hypervitaminosis but rather of some substance in the wheat germ oil.

Lactoflavin (Vitamin B₂) in Retina in Different Conditions of Adaptation. M. Zewi.—p. 923.
*Foramen Ovale Cordis Apertum and Its Role in So-Called Paradoxical Embolism. L. Löfgren.—p. 937.

Subconjunctival Epithelial Cyst and Trachoma.—Werner describes an epithelial cyst in the conjunctiva which was about 1.5 cm. long and 0.3 cm. thick. Nine years earlier trachomatous granulations in the same eye had been treated by expression. In the connective tissue of the lids, numerous trachoma granulations were still seen. He ascribes the tumor to epithelial proliferation or to fold formation in the connective tissue, probably due to the inflammatory trachomatous process.

Role of Foramen Ovale in Paradoxical Embolism.—Löfgren says that in 785 necropsies (in 615 males and 170 females, including no children under the age of 10) foramen ovale cordis apertum was found in 120 cases, or 15.3 per cent. It varies considerably in size and form, the usual diameter being from 2 to 5 mm., while the largest opening is passable to a finger. Unlike a number of other anomalies in the heart, it does not affect physical development or length of life. According to Frey, thrombi in cases in which there is open foramen ovale most often pass from the right auricle to the right ventricle. However, when there is a pulmonary embolus simultaneously with open foramen ovale, possible thrombi in the right auricle which are of the size to pass the foramen ovale are, because of the changed conditions of pressure, passed by way of the left auricle and ventricle into the arterial circulation, where small, otherwise harmless, thrombi may cause death. In cases with the open foramen ovale and simultaneous pulmonary embolus, thrombi as a rule pass through the foramen. Thrombi may often remain in the open foramen, and crossed air and fat emboli may occur in cases with open foramen ovale.

Tuberculous Meningitis During Pregnancy: Case. H. Harpøth.—p. 739.
After-Examination of Lupus Patients in Jylland. S. Lomholt.—p. 740.

Treatment of Gonorrhea with Sulfanilamide.—Kristjansen and Kaalund-Jørgensen treated 118 patients with sulfanilamide from December 1937 to May 1938. The by-effects were grave in only one case (hepatitis). The treatment was effective in forty-one (82 per cent) of the fifty women, none of whom were observed for less than six weeks. Three cases are listed as possible "late recurrences." The results were good in twenty-nine (85 per cent) of the thirty-four men with complications. Good results also followed in one of the nine men with infections of less than three weeks' duration, and in thirteen of the nineteen with infections of more than three weeks' duration. The author found that patients resistant to sulfanilamide were later easily affected by other treatment. Recurrence in men after treatment with sulfanilamide was within fourteen days after ending treatment; late recurrences in men were not seen.

SOME FEATURES OF PRESENT DAY DIAGNOSIS

JAMES B. HERRICK, M.D.

CHICAGO

To have been elected president of the Congress of American Physicians and Surgeons is an honor that is highly appreciated and for which sincere thanks are here tendered. The distinguished men who in the fifty years of its existence have held this position almost without exception in their presidential addresses discussed topics concerning which they had first hand knowledge derived from personal experience. In conformity with this wise precedent, I shall speak from the point of view of a clinician whose fifty years as medical practitioner and teacher have been intimately and chiefly concerned with the patient. I shall confine my remarks to one phase only of clinical medicine; viz., diagnosis and some of its present day problems.

THE PROCESS OF DIAGNOSIS

Can anything new be said concerning diagnosis? Have not its principles and its methods been firmly established for centuries? Cannot one predict that for generations to come physicians will still be trying to answer the question "What is the matter with the patient?" by following the time honored procedure of considering the hereditary, environmental and personal history; the story of the present complaint; the physical examination; the reports of laboratory; instrumental and therapeutic tests; the advice of specialists; finally, the assembling of all these facts, their careful analytic and synthetic study, and their summation in a logical conclusion?

Why, then, bring up a subject so trite?

I might plead the necessity of repeating the well known from time to time lest it be forgotten; also the importance of the topic, for the desire to make a correct diagnosis by which the way is prepared for rational treatment is the most compelling motive in the practice of medicine. A more potent reason, however, is that diagnosis today presents problems that are quite different from those of even a decade ago, for diagnosis is not as stable as it is often thought to be. The order of procedure may remain the same but technic changes. Every addition to medical knowledge carries with it the necessity of a revision of the methods of diagnosis. The microscope, bacteriology, x-rays, applied chemistry, endocrinology, these and many other factors have combined to make diagnosis far different from what it was when it was chiefly a matter of scholastic musing,

adherence to tradition, and idolatrous veneration of the fathers of medicine. These newer facts in medicine and cognate sciences, facts that aggregate a huge mass, have in some respects rendered diagnosis simpler and more accurate; in other respects, more difficult and more complicated.

At present diagnosis as well as medicine in general is in a good deal of turmoil, with many problems pressing for solution. These will not be solved, though the solution may be helped, by resolutions or pronouncements of medical organizations, reports of special committees or recommendations of foundations of various kinds, no matter how sincere and searching the efforts of any or all of these bodies may be. They will not be solved by the utterance of epigrams like "train for power," "back to Hippocrates," "back to Galen," for, like most wise sayings, these are but partial truths. The answers will not be found by cloistered meditation in the library or by mere sitting in at a pedagogic conference, or by indulging in day dreams in which the ideal and even the idyllic are permitted to becloud reality. Diagnosis is an eminently practical process, concerned with human beings, with pain and bleeding, with germs and fever, with failing function of organs, with threatening death. Theory and science are involved, of course. But diagnosis implies the application of theory and science. As electrical engineering needed an Edison as well as a Faraday, so modern medicine is a debtor to Lister as well as to Pasteur.

The solution will come mainly through evolution, by the process of trial and error based on the experience of general and special practitioners, research workers in ward and laboratory and on the reaction of the public, i. e. the patients themselves—and the patient, let it be noted, is the party whose interests are paramount. All these other agencies that I have mentioned may be helpful though not decisively final. A frank statement of difficulties, with tentative suggestions for remedies, may also be helpful though also indecisive. It is in such a hope that, repeating much that has been said by others as well as by myself, I venture to discuss here some—by no means all—features of modern diagnosis. By speaking often in the first person singular it will be evident, I trust, that I am not presuming to express in this address any but my own opinions.

DANGERS FROM IGNORANCE

A prolific cause of errors in diagnosis is ignorance, varying in degree, of course, on the part of the practitioner. He may be lacking in information because he has no urge to study, has never been taught to study or perhaps lacks the ability to study. He made a mistake in his choice of a profession; the medical school erred in encouraging him or even permitting him to be a physician. He fails to keep abreast of the times by

reading and by conferences with his colleagues. He loses touch with the laboratory and the morgue. He is either a forceless, inefficient man who, feeling his inferiority, attempts but little and does that poorly or he may be one who, possessing only the little knowledge that is a dangerous thing, becomes a menace because he is blissfully unaware of the meagerness of his knowledge. Where better informed and wiser men would fear to tread, he rushes in with scalpel or harmful drug or half-baked theory, before he knows the real nature of the ailment he has been called to treat.

The threat from this type of doctor who is unaware of his limitations is one of the strongest arguments for intensive work in undergraduate and intern days, e. g. the exhaustive study of a case or a group of cases through ward, laboratory, operating room, perhaps the deadhouse. Or it may be a problem studied in some department, such as pathology or physiology. Such work will inculcate the principle of thoroughness, the importance of reading original articles and monographs and not merely textbooks. By such intensive work the student learns how medical knowledge is acquired and what are its present day deficiencies. He is better able to distinguish between theory and fact; he gets rid of the incubus of unthinking veneration for the printed word. He learns to reason and judge for himself, though the responsibility for training in independent thinking should not fall primarily on the faculty of the medical school but rather on the school of arts and sciences, a point dwelt on in 1900 by H. P. Bowditch in his presidential address before the fifth session of this congress.

This "majoring" in the medical school has been opposed by some who, in their fetish-like worship of the old type of general practitioner, not realizing or ignoring the tremendous changes that have taken place, argue that the student should not be permitted to do any intensive work because it smacks of specialism. To these objectors specialism is anathema. Is it not time that this out-moded attitude be given up?

The principle of majoring should be carried over into the life of practice. Unless this is done, the practitioner goes stale. Concentration on some subject with the accompanying sense of mastery and the resultant zeal for the new is what will save doctors from remaining mere drudges, with no pleasure in their daily grind, with no sense of progress. This is not specialism in the strict sense. It is expertness, superior knowledge and skill. The process is not a narrowing one; on the contrary, it is broadening.

There is another advantage that will come from this intensive study. It will make clear to the doctor that he has not performed his whole duty when he puts the proper caption on a disease. He should know the cause of such disease and the manner in which such cause has operated in the particular case in hand. He should be familiar with the alterations in anatomy and physiology that are involved, should have knowledge of the natural course of the disease, the best way of handling it, the dangers to the patient and to others, the social and economic import of the illness. This implies well directed instruction on the part of the teacher, much observation and wisely utilized clinical experience on the part of the practitioner.

But it is impossible for even the diligent and bright doctor to know all. There is too much of it. He must select certain topics toward the mastery of which his major efforts are directed. The medical school may,

perhaps should, offer him the opportunity of choosing from a wealth of courses. It should guide him in selecting what seems most suitable to him as an individual. It should compel him to select what is essential to physicians as a class, that which teaches the broader, fundamental principles and the facts that are necessary for his everyday work as a practitioner and for his future development. All this is no easy task. The problem of what constitutes wise guidance for the undergraduate, postgraduate and graduate student is being given careful, expert consideration by practitioners themselves, by medical schools, by able committees of investigation and by such bodies as the Council on Medical Education and Hospitals of the American Medical Association, which has functioned so long and so well. Much progress has already been made.

It may be added here that many of us who are older magnify the difficulty that the undergraduate or young practitioner has in grasping even a respectable fraction of the huge mass of knowledge that has accumulated in the last fifty years. We recall the struggle we had when, bewildered, we tried to understand the new that was then in the chaos of formation. We forget that many questions which were at that time subjects for argument and investigation are now settled. The tenets of bacteriology are approved, aseptic surgery and midwifery are established practices, the morphologic and chemical examination of the blood, the x-rays are accepted as helpful aids. Students of today have similar though different problems to face, but the difficulty of learning much that we struggled with is not as forbidding as we often think.

NEED FOR HELP

Ideally the doctor should be able by himself to interview and examine his patient, make the instrumental and laboratory tests and reach a decision as to diagnosis. This ideal is rarely realizable, for our doctor, even though a paragon, cannot do these things unaided. How can he best get help? Physicians are already answering this question by methods determined by individual needs, opportunities and experience. One takes an assistant or associate. Another joins colleagues in hiring and supervising a competent technician or he becomes a member of a group or clinic that may include specialists of several types or he avails himself of the services of his hospital, the municipal laboratory or a properly conducted private laboratory.

Yet these plans have certain weak features. The further away the doctor is from the laboratory, the instrument, the consultant and, most important of all, from the patient, the greater is the likelihood of error. The doctor by eliciting the history himself may learn as much from the way a patient answers questions as from the answers themselves. If the doctor sees for himself the x-ray film, the stained blood under the microscope, he has a more nearly correct impression than that conveyed by merely reading the report of the consultant or assistant. Also many instruments and special tests are not as precise as they are sometimes thought to be; the technician is prone to err in interpreting what he sees in the laboratory just as is the doctor when he tries to translate into pathology what he observes at the bedside. And there is a real danger from overspecialization. These topics have, however, been so frequently and so well discussed that to take them up further in this paper would be needless repetition. From the standpoint of diagnosis, may from that of medical practice in a broader sense, may we not

accept the specialist, the laboratory and some form of group practice as *faits accomplis*? But first the specialist, the laboratory, the group must show by certification or some other test that they are worthy to offer reliable aid to the practitioner.

EXTENT OF THE EXAMINATION

There is another feature of modern diagnosis of minor value, perhaps, that is worth consideration. Not all patients need the thorough going over that they are often given. The family doctor is familiar with the past health history of his patient. His problem is that of the present illness. With a few questions, a snappy physical examination, he recognizes an attack of erysipelas or measles or acute cardiac failure. He may use the thermometer, the blood counter or the rubber glove but he sees no call for the Wassermann test, the x-ray film or the electrocardiogram. He is well aware that everyday symptoms that seem simple may be due to disease that is serious. Headache may mean tumor, rapid pulse may be due to perverted thyroid action, dizziness may come from pernicious anemia, the acute indigestion may mean appendicitis, carcinoma of the bowel or coronary thrombosis. But he feels that many patients with stomach and bowel upsets, for example, and other everyday ailments with no urgency about them are quite properly examined and treated for a time on the basis of a provisional diagnosis. They need not be rushed to the hospital for study of stools, tonsils, teeth, sinuses, blood chemistry and the like. He agrees with the Mackenzie that, when one wishes a flat tire fixed, one resents the advice of the garage man that a thorough overhauling of the car is necessary. It is here that there comes into play not alone the knowledge possessed by the physician but also his discriminating good sense and his mental acumen kept sharp by experience. He will realize that, when life may be urgently threatened by waiting, the safety of the patient must incline the decision to immediate action. To be informed is to avoid dangerous errors in practice, said Billroth. Knowledge and above all else wisdom are here at a premium.¹

I wish to utter a word of caution as to the way in which diagnoses are sometimes made in connection with the periodic examinations or health check-ups that are so popular today. In cases with obscure symptoms that possibly portend evil, each and every form of examination may be indicated. So too there can be no quarrel with the doctor who feels that he can earn an honest dollar if he yields to the demand of his intelligent patient that, regardless of time or expense, a complete examination be made and a detailed opinion be rendered as to the state of health. Yet even here caution is necessary. Some investigations, e. g. bronchoscopies, ureteral catheterizations, exploratory punctures, allergic tests, are not entirely devoid of risk. Nor is it always wise to discuss with an already apprehensive patient symptoms that are trivial and negligible. Anxiety neuroses and phobias are easily aroused. Such mental upsets can be avoided if the doctor understands patients as well as disease and has the ability to convey truthful

1. The same tendency to advise unnecessary examination is seen in the office work of general practitioners and specialists and in the group or clinic. Examination by x-rays, the electrocardiograph or by the Wassermann or metabolism test would rarely add usable knowledge in the case of a patient with a rheumatic mitral stenosis and a moderate degree of congestive heart failure. On the other hand, a patient with a leaky aortic valve and threatening heart failure may present an entirely different problem. The cause of the lesion—rheumatism, syphilis, arteriosclerosis, hypertension—the possibility of aneurysm or even of an error in diagnosis with a congenital defect or a coarctation of the aorta causing the symptoms may make one or several of these tests imperative. Proper therapy may depend on their results.

information in a way that does not terrorize. Fortunately, too, some patients are well poised and not easily disturbed mentally. A woman of 50 asked my opinion of the report of twenty-five pages that had been handed her as the result of a study of her case in a reputable clinic. Fourteen disease conditions had been found and were duly listed. As I finished reading I said "Well, what did you think about it all?" "Doctor," she replied, "if there had been two or three conditions reported it would have scared me stiff. But when I saw fourteen I just laughed." A pretty sensible view to take of some of these reports.

To tell a patient what ails him requires much understanding of human nature and much tact. One should be careful not to alarm unduly or to convey a wrong impression. Emerson has said "It is not the fact that imports but the effect or the impression of the fact on the mind." To tell a patient that he has a leaky heart valve or syphilis or diabetes may be to state a fact. If the effect of this unexplained statement is to convey to the layman that he has a disease that is hopeless, that will progress relentlessly to an early fatal issue when such is not the case, one has by stating a fact conveyed a wrong impression, has told an untruth. One must adapt the statement to the intelligence of the hearer and by explanation and qualification make it convey the truth that is necessary for the proper understanding of the condition and the carrying out of the advice that is to be given.

Many other features of diagnosis that present minor problems might be discussed did time permit and were it profitable to dwell on what would be agreed to without argument. Among these may be mentioned the importance of having no preconceived notion as to what is the matter when one tackles a case of illness. One should go in with an open mind, though one should not keep the mind constantly open. As G. K. Chesterton said, "The object of opening the mind as of opening the mouth is to shut it again on something solid."

Then there is the doctor whom we all know who lets his diagnosis depend too much on his pet symptoms. A peculiar luster to the eye, a tint of the skin or a special brand of cough or of pain and the doctor's mind is, if not already made up, at least strongly prejudiced. There is the bluff doctor who breezes in and with a rough and ready air, after a cursory examination, makes a cocksure diagnosis that may turn out to be correct. His more scholarly and scientific colleague sarcastically comments that this doctor doesn't know enough to hesitate or be in doubt.

One might discuss the diagnosis by exclusion, or the problem presented when two or more diseases are present rather than one, or the importance of revision of a diagnosis. One might consider further than has been done the perils from emphasizing one of the diagnostic procedures at the expense of others. "Doctor," said a patient to me, "I hope you will be different from the many physicians whom I have consulted. I hope you will examine the x-ray films less and me more." There is a good text for a sermon: in examining the films do not overlook the patient.

DANGER OF TOO MUCH KNOWLEDGE

There is one feature concerning which I wish to speak a little more at length. To state it paradoxically, some physicians know too much to be good diagnosticians or safe advisers. They have more knowledge than they can well handle; they are "suffocated beneath

a dead weight of erudition." A doctor of this type knows a multitude of facts. But these facts and their arrangement in the doctor's mind resemble the motley collection seen on the medicine shelves of the bathroom. To be of value, facts, whether they are the result of planned research or of accumulated experience, must be seen not in their isolation but in their relation to other facts. President Neilson of Smith College expressed it the other day when he said that "truth lies not in facts but in the relations between facts." The physician or surgeon may lack the ability to distinguish between major and minor symptoms of disease. He fails to realize that there are what might be called the nonessentials of diagnosis. One of these nonessentials held too close to the eye may obscure the central field of vision and the essentials may not be seen. He may be so overconscientious as to be timid, so obsessed by the laudable desire to be thorough that he putters over minutiae and overlooks the obvious. Valuable time may be lost in waiting for the blood count, the icteric index, the electrocardiogram, the x-ray film, and the golden—perhaps the arsenical—opportunity for prompt action slips by, the favorable time for operation, for giving antitoxin, or prescribing bed rest is lost.

There is such a thing as being too particular.² We may apply to medicine what Mr. Justice Cardozo said about the law: "There is an accuracy that defeats itself by overemphasis of details." At times this unfortunate stressing of the incidental is a defense reaction, a desire to appear judicially minded and to reach no conclusion until all the evidence is in. Again, following Justice Cardozo, this is an invertebrate habit of mind which thinks it is impartial because it is undecided and which regards the judicial attitude as that which refrains from judging.

To what extent should the doctor seek for these less common or even out of the way signs? How can he assess them at their proper value? Should they be taught to the undergraduate? It is not easy to give a categorical yes or no answer to these questions. As the children say, Why, that depends.

The answer will depend much on the purpose for which the diagnostic study is made. If research is the prime object, phenomena apparently the most trivial may profitably be sought and recorded in minutest detail. No preconceived notion as to their insignificance should exclude their consideration. The results may show they are of great worth. The same is true if the doctor is trying in every way to perfect himself—as he should—as a keen observer and skilled diagnostician. He should learn their value by trial. If, however, the object of the examination is to decide promptly what is the matter with the one particular individual who is before him so that this individual may be treated rationally and without delay, many symptoms may be virtually ignored, to be considered only if help is needed to remove a lingering doubt. A too meticulous concern with the finer points of diagnosis may easily lead good clinicians to lose their sense of proportion and perspective.

It would be helpful if symptoms might be classified from pathognomonic or positive—tubercle bacilli in the sputum or urine, crepitus and displacement in fractured bones, shadows like those of gallstones in the

film—down to those only rarely present or of lesser value. Extreme caution is here necessary. Even bone crepitus may be simulated by conditions other than fracture; the shadow confidently regarded as due to gallstones may be cast by a calcified gland. And symptoms low down in the scale may at times assume increased importance; for minor symptoms are by no means to be scorned. Take the case of pulmonary tuberculosis: The diagnosis is regarded as certain if the bacillus is found in the sputum. The x-ray film is a second major reliance. No further symptoms are necessary for a positive diagnosis. Yet in cases in which the x-ray revelations are doubtful and in which no tubercle bacilli are found, other symptoms are by no means negligible: cough, rales, emaciation, anemia, fever, rapid pulse. And such symptoms may be of importance from another point of view. They may enable one to estimate the gravity of the illness more definitely than is possible by the x-rays or by the study of the sputum, for the number of bacilli or the extent of the diseased area as revealed by the x-rays do not always declare the seriousness. Such symptoms, therefore, should be discussed before students and considered at the bedside.

An extreme view of this aspect of the nonessentials that I have presented is taken by some who say that undergraduates should not be taught the unusual, the less important or the imperfectly understood in diagnosis. Why, they say, should the practical man at the bedside be concerned with systolic apical murmurs? They generally mean little and are often misinterpreted. Why should he bother about slight variations in blood pressure, poorly understood features of x-ray films? Diagnosis based on fundamentals and essentials is "good enough" for the ordinary doctor.

This extreme view seems to me a mistaken one. As I have said, the dangerous doctor is the mediocre man who is unaware of his own limitations and the pitfalls of practice and does not know the unusual when he meets it. The most reliable man is he who knows the most and knows his own ability and his limitations.

Another reason why one may object to this "good enough for the ordinary doctor" attitude is that, while some symptoms like the apical systolic murmur, to use this as an example, often have no sinister meaning, sometimes they mean much. Because physicians frequently misinterpret is not a valid reason for ignoring the murmur or for discarding the stethoscope and all it stands for. It is rather an indictment of the profession in general for lack of accurate knowledge concerning this murmur. Is it not the duty of the schools and the leaders in medicine themselves to learn more about such things and to teach more efficiently?

The wisdom of the policy of teaching in the undergraduate courses only the essentials of medicine is debatable for another reason. By compulsory education in our public schools all children may be taught to read and to write a legible hand. The standard of the mass is thus raised. But the child so taught does not necessarily become an educated man in the higher sense of that term or an author or even a discriminating judge of good literature. This has been pointed out by an acute observer, Prof. Wilbur Abbott, who shows how popular education may lower the standards of the best writers. For these writers unconsciously or consciously are led to write down to the level of the reading public, now become so enormous in number, with which is the market for their wares. Many of the histories and biographies of the day, best sellers

2. Bichat expressed it when he said there were two perils equally to be feared: that of particularizing too much and that of generalizing too much. The second, he said, leads as well as the first to false results. (Quoted by Bouillaud, *Traité de maladies du cœur*, p. 254).

by virtue of attractive style and the atmosphere of romance, are yet lacking in the elements that should, and formerly did, mark truthful, scientific history and biography. In a similar manner may not the plan of educating doctors only in the essentials, the three R's of medicine, involve a lowering of the standard for the mass of doctors? May not this in turn drag to a lower level the superior man, the specialist, the investigator?

RESEARCH

Then, what seems to me an unfortunate attitude has been taken by some who say that there should be a sharp line of demarcation between the ordinary practicing physician, whose duty is to do the daily grind of telling what is the matter with and treating the patient, and a higher type of scientific clinician whose function is investigation. Sir Thomas Lewis, who so richly deserves the distinguished medal for his research service to medicine and whose opinion on problems of practice cannot be lightly brushed aside, favors this distinction. The one type of doctor would be concerned with what he calls "curative medicine" ministering to the immediate needs of sick individuals, and the other with progressive medicine or "clinical science." The latter group would search for new facts, the former would simply apply knowledge already known.

I agree with nearly all that Sir Thomas says in his stimulating paper of eight years ago.³ But it seems to me that there is an implied slur on the aims and abilities of the general practitioner that should not go unchallenged. There are many poor practitioners, one has to admit. But is it fair to judge all practitioners by the poorest, even though they be many? Not all practitioners, not even a majority of them, are of mediocre ability; not all are merely commercial in their aims; not all make their diagnoses by "no process of mental reasoning" but by a sort of glorified intuition derived from their experience as craftsmen in the art of guessing, *ars conjecturalis*, to use the expression of Celsus; not all drop their contact with the laboratory and lose the spirit of research as soon as they are graduated. There can be no objection to the plan of intensive investigation of clinical problems by all-time qualified men in wards entirely under their control. No reproach can be cast on workers in pure laboratory research or in the most refined type of clinical investigation. All power to the small number who are qualified to carry on work of this kind, and richest opportunity! But arbitrarily to put into the class of the inferior the bright, industrious, well informed practitioner, specialist or part-time hospital physician or teacher who, imbued with the spirit of research, sees in every new and interesting case or group of cases a small problem for investigation—what is the matter with the patient, with all that diagnosis implies—seems unfair and unjust. It is discouraging to those who make up, and must of necessity for several years make up, the bone and sinew of our profession (at least in the United States and Canada) to be told that they must abandon hope who elect to enter the ranks of the general practitioner. Moreover, is it not rather extravagant to declare that little or nothing new can be expected in the future from the "curative" practitioner or specialist? That in making bedside observations he will be working in a field whose fertility is all but exhausted? That there is no prospect that any future Addison, Charcot or Skoda will add anything of value

to medicine? That he must be content to do the necessary daily drudgery, that the "clinical science" investigator will do what counts?

It seems to me that these views of Sir Thomas are not sound.

CONCLUSION

In summing up, I realize that there are in this paper omissions and inconsistencies. Nor can I pretend to have offered completely satisfactory solutions to the problems of present day diagnosis. The train of thought, not always connected, is that diagnosis—a process that is necessary in the everyday life of the practitioner of medicine, using the term "diagnosis" as meaning more than a perfunctory labeling of a disease—implies the application of more knowledge than any one human being can acquire, remember or properly utilize. The doctor must then have help which makes qualified laboratories and qualified specialists singly or in groups a necessity.

There has been pointed out the importance of perspective in diagnosis, the ill effects that come from being too particular regarding minute details, yet it has been contended that the practitioner must know of their existence, for minute details may mean much.

Reference has been made to the unwisdom of teaching students merely the so-called essentials. It has been pointed out that such a course may not only make less efficient practitioners but lower the morale and high standards of productive research. The value of "majoring" for the undergraduate and practitioner has been stressed.

I have expressed regret that the line of cleavage that has to be drawn—and such a line is a necessity—between the practitioner and the investigator in clinical science should be so sharply and so heavily drawn as unduly to discourage the one worker and relatively, at least, unduly to exalt the other.

It has seemed as though in the last few years there has been a tendency toward better relations between practitioners, specialists, laboratory investigators, hospitals for the care of patients, hospitals and institutes whose primary object was research, and that harmony and a spirit of cooperation have been gradually displacing the old antagonism, jealousy and misunderstanding. I fear that insistence too sharply on the separation of these two types of doctors may lead to the development of a deadening inferiority complex in the one type of worker and of a superiority complex in the other that will not improve the efficiency of either group and that in the end may have unfortunate results both in the practice of medicine as an art and in the science of medicine in the way of productive research. I endorse most heartily the plea that has been made by Soma Weiss⁴ for closer relations rather than wider separation between all these groups in the belief that cooperation will be mutually beneficial.

These problems, to repeat, will be worked out largely by evolution, by trial and error at the bedside of the patient in the home and in the teaching hospitals of medical schools. Their study by capable practitioners and educators has already helped toward clarification. All these efforts should be continued and encouraged.

Finally, unless there is now impending or shall later come upon us a second Dark Age in Science when all progress will be at a standstill, these problems never will be settled. For medical knowledge is not static, it is in a state of flux; new facts and new generalizations

are constantly being established, new social and economic theories and practices are being advocated and adopted. All this means there will have to be frequent readjustments. One may repeat what was said a hundred years ago by a wise clinician, Peter Latham: "Whenever in medicine anything like a discovery has been made, anything which has had the show of a principle or a law, a large surrender of cherished opinions has always followed, and knowledge has seemed to begin its career afresh from a new starting place." May I venture to predict and to express the hope that one hundred years from now medical knowledge will seem to begin its career afresh from a new starting place, for it will still be progressing.

EVALUATION OF DRUGS COMMONLY EMPLOYED AS DIAGNOSTIC AIDS IN CLINICAL MEDICINE

STACY R. METTIER, M.D.

AND

CHAUNCEY D. LEAKE, Ph.D.

SAN FRANCISCO

The administration of a drug to estimate abnormal structure or function of an organ in the body is becoming increasingly common as a diagnostic aid in medicine. Many of the drugs in use for this purpose are administered by a technical assistant and, through popular usage, have come to be looked on merely as playing a role in a laboratory procedure. Drugs so used, therefore, have tended to lose their identity in the minds of physicians as substances capable of inciting specific tissue and cellular activity. Although much has been added to our knowledge of pathologic physiology by their clinical application, their use is not without danger. The use of a chemical in diagnosis is not justifiable if its possible toxicity outweighs the value of the information which may be derived.

For many years clinicians and physiologists have attempted, by the use of certain drugs, to devise means of determining altered organic function, of diagnosing specific tissue damage and of arriving at an accurate prognosis. A great deal has been learned, for example, about diffuse disease of the liver and kidneys, particularly in the late stages, but much is to be learned concerning methods of diagnosis of disease in its early stages when treatment may be more effective.

What, then, is the present status of drugs used as diagnostic aids? What toxic effects are to be expected? What are their limitations and contraindications? Are data obtained from diagnostic tests superior to information gained by a carefully taken history, a thorough physical examination and a few simple laboratory procedures? Answers to these questions must be sought by a critical analysis of methods in use and by a knowledge of the action of drugs employed in diagnosis and of the idiosyncrasies of the particular patient concerned.

Comprehensive knowledge of the action of chemicals in the body will suggest to the discerning and ingenious physician many diagnostic uses. Thus the paralyzing action of atropine on the vagal endings in the heart may be used to differentiate heart block from brady-

cardia due to excessive vagal tone. Similarly, detailed knowledge of the mode and rate of excretion of drugs from the body may be judiciously applied to diagnostic problems, as when Rowntree and Geraghty¹ made their classic study of phenolsulfonphthalein as an aid to the estimation of renal function. Again, recognition of the opacity of iodine to roentgen rays has permitted the building of certain drugs to specification to meet particular diagnostic problems associated with the visualization of body cavities. Thus Forrestier and Sicard² took advantage of the fact that unsaturated physiologically inert lipids combine with enough iodine to be useful with the roentgen ray to visualize pulmonary cavities or even the spinal canal. By using iodine to halogenate phenolphthalein, Cole, Copher and Graham³ changed a laborious and indirect liver excretory test to a roentgen procedure helpful in determining not only liver excretion but also the presence of the functioning gallbladder. And by iodizing relatively simple organic compounds which are rapidly excreted by the kidney, Zwick⁴ developed efficient drugs for the roentgen visualization of the whole urinary tract.

A point of interest with regard to many drugs used for diagnostic purposes is expense. All organic compounds containing iodine are expensive, because iodine is costly and because it requires sound technical skill to maintain uniform composition in iodized compounds.

The chief drugs used for diagnostic purposes are thoroughly described in New and Nonofficial Remedies. Particular care is taken by the Council on Pharmacy and Chemistry of the American Medical Association to call attention to toxic symptoms or untoward effects from the use of these drugs.

Drugs for specific diagnostic purposes may be classified according to the body systems to be examined. Such a classification is suggested in the accompanying table. Or they may be classified according to the application of action: (1) those with specific pharmacologic effect, such as histamine to stimulate gastric secretion; (2) those with specific fates in the body, such as dextrose for testing the carbohydrate tolerance of the liver; (3) those which are selectively and quantitatively excreted by certain organs, such as phenolsulfonphthalein for testing renal function or "rose bengal" for estimating the efficiency of the liver in removing a foreign substance (dye) from the blood; (4) those which are opaque to roentgen rays and are only slightly or slowly absorbed into the body, such as barium sulfate for roentgenographic visualization of the gastro-enteric tract or iodized oils for roentgenologic examination of the lungs or spinal canal; (5) those which are opaque to roentgen rays and also selectively and quantitatively excreted by certain organs, such as phenol tetraiodophthalein for roentgen visualization of the gallbladder, and sodium ortho-iodohippurate for roentgenologic examination of the urinary tract, and (6) those which permit roentgenographic contrast and are rapidly absorbed, such as ethylene for examination of the cerebral ventricles.

Read before the Section on Pharmacology and Therapeutics at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

ROENTGENOGRAPHIC VISUALIZATION OF
BODY CAVITIES

After several years of great enthusiasm in the use of iodized oils for roentgenographic visualization of various body cavities, physicians have come to realize the slowness with which these agents may be absorbed and the consequent danger of foreign body reactions at the point where they may lodge. Untoward reactions following the injection of iodized oil into the subarachnoid space of the spinal canal does occur, as has been recently reported by Brown and Carr.⁵ The risk of injury from intraspinal injection of iodized oils for localization of cord tumors should be minimized, for example, by careful efforts to remove all trace of the oils at subsequent operation. The Council on Pharmacy and Chemistry has issued a comprehensive report on the history, scope and limitations of iodized oils for roentgenographic visualization of body cavities.⁶ This

tions for the purpose than is the case with any other diagnostic agent. Giving full efficiency, it is practically free from untoward effects, is not absorbed unless there is ulceration, is easily administered and is not expensive.

Similar satisfaction cannot be expressed with the drugs used to promote gastric secretion for analysis. Neither alcohol nor histamine is as safe or efficient as may be desired. Bloomfield and Polland's⁹ careful studies on the diagnostic use of histamine clearly indicate its scope and limitations. It would seem that acetylcholine or beta-methyl-acetylcholine might be surveyed clinically from the standpoint of diagnostic use for collection of gastric juice. They have been employed to assist in the diagnosis of colonic conditions.

DRUGS USED TO TEST EXCRETORY FUNCTION

Criteria for the recognition of impaired excretory function of an organ have accumulated slowly during

Acceptable Drugs for Diagnostic Purposes

Body System and Purpose	Drug	Dose and Administration
Body cavities: For roentgenographic visualization..... (For scope and limitations see THE JOURNAL Dec. 3, 1932, p. 1946)	Campidol emulsion N.N.R. Lipiodol N.N.R. Lipiodol radiologique ascendant N.N.R. Lipiodine N.N.R. Ethylene U.S.P.	1-20 cc. for retrograde urography 1-5 cc., depending on use 1-2 cc. intraspinally 5-20 cc., depending on use 10 cc. intraspinally
Eye: For dilating pupil to permit retinal exam- ination For detection of corneal lesions.....	Cocaine hydrochloride Eucatropine N.N.R. Homatropine hydrochloride N.N.R. Fluorescein soluble U.S.P.	1-2 drops 1 per cent solution 2 drops 5-10 per cent solution 2 drops 1 per cent solution 1-2 drops 1 per cent solution
Gastro-enteric tract: For collection of gastric juice..... For roentgenographic visualization.....	Alcohol "C.D." Histamin Barium	50 cc. of 7 per cent solution 0.5 mg. subcutaneously 100-150 Gm. orally
Kidney function	Phenolsulfonphthalein U.S.P.	1 cc. of 0.6 per cent solution, intramuscularly or intravenously

report should be studied by physicians contemplating the use of these agents for the first time.

Using gaseous agents for providing contrast in the roentgenologic examination of the ventricles of the brain is also a hazardous procedure. Aird's⁷ thorough search for a suitable gas resulted in the choice of ethylene. This is a great improvement over air, but untoward effects are still possible. If they occur, it is tempting to blame the anesthesia used and to forget the risks involved in introducing a relatively large volume of gas into the cerebrospinal canal.

GASTRO-ENTERIC TRACT

Cannon's⁸ brilliant pioneering x-ray investigation of intestinal motility led to the introduction of a drug, barium sulfate, which remains closer to ideal specifica-

the past few decades. By means of the ingestion or the injection of tinctorial substances, biologic products, and radiopaque preparations introduced recently,¹⁰ sufficient information has been accumulated to permit the physician to identify the impaired organ and to determine to some extent the degree of damage to which it has been subjected.

One may question, however, the justification for using so dangerous a drug as thorium dioxide for such a purpose under any circumstance.

Drugs used to determine the excretory function of the liver are limited almost entirely to a few dyes whose value lies in the ability of the liver to remove them from the blood stream into the bile. The two most commonly used dyes, rose bengal and bromsulphalein, when retained in the blood plasma, may be visualized and measured quantitatively by colorimetric methods. The

technic of the rose bengal test was described in 1924¹¹ and, as first proposed, the degree of excretion of the dye was estimated by colorimetric readings. Althausen, Biskind and Kerr¹² recently have shown that the test could be more sensitive and the limits of the test 5 per cent lower by using the spectroscope instead of the colorimeter. The experience obtained from the performance of this test on 302 patients at the University of California Hospital have been reported recently.¹³ For the purpose of this study, 10 cc. of a 1 per cent solution of rose bengal (di-iodo-tetrachlor fluorescein) in physiologic solution of sodium chloride was injected intravenously. A specimen of blood was removed at two minutes to be used as the standard for maximum distribution of the dye in the blood stream. The results were classified according to the amount of the dye retained in the blood plasma. Tests showing a retention of from 55 to 65 per cent in eight minutes and from 35 to 45 per cent in sixteen minutes were considered as slightly positive, those from 66 to 75 per cent and from 46 to 55 per cent respectively as moderately positive, and those in excess of 75 and 55 per cent respectively as markedly positive. In intrinsic diseases of the liver this test was shown to be extremely satisfactory, since retention of the dye in patients with acute hepatitis showed a positive result in 94 per cent of cases and in patients with chronic hepatitis a positive result in 96 per cent of cases.

The dye bromsulphalein has come into more general use than rose bengal as a test of the excretory function of the liver. In the performance of this test 5 mg. of the dye per kilogram of body weight¹⁴ is injected intravenously. At the end of one hour a single specimen is removed, which eliminates the three samples of blood required in performing the rose bengal test. The retention of 10 per cent or more of the dye is considered abnormal and indicative of liver damage. Results comparable to those obtained with the use of rose bengal have been reported by Magath.¹⁵ This author found a retention of bromsulphalein in 96 per cent of cases in which there was evidence of parenchymal hepatic damage.

It has been stated¹⁶ that the retention of dye may more or less parallel the degree of icterus. However, some modification of this statement must be made, depending on the type of structural alteration of the liver. In patients recovering from "catarrhal jaundice" the rose bengal test may show a return to normal function of the liver while the icterus index is still considerably elevated. Furthermore, it is well known that hepatic damage may exist without jaundice and ascites. Such alteration may be suspected in a patient with a slightly enlarged liver, but impairment of function may

be determined by the dye excretion test. An example of this situation is given in the following case:

Enlarged liver, clinically asymptomatic; macrocytic hypochromic anemia; profuse menses; impaired hepatic function.

History.—M. M., a married woman, aged 33, Italian, came to the medical division of the outpatient department of the University of California Aug. 4, 1937, because of weakness, loss of weight and profuse menses. For eight months prior to entry a variety of symptoms had developed, among which were irregular episodes of profuse vaginal bleeding and generalized pruritus. An intractable insomnia had developed and she had had hot and cold flushes passing over the body. There was a tendency toward nervousness and excessive perspiration. Since childhood it had been her custom to consume not less than 1 quart of wine daily. In recent years this amount was frequently greatly exceeded and on occasions was supplemented by the use of whisky.

Examination.—The patient appeared well developed, in no obvious distress but with slight evidence of loss in weight. The skin was pale, warm and moist. Lymphadenopathy was not demonstrable. The thyroid gland was not enlarged. The liver edge was felt 4 cm. below the right costal margin. The edge felt smooth, was not tender and had a sharp border. There was a small mass adherent to the right lateral border of the uterus.

Laboratory Procedures.—Examination of the blood showed red blood cells 3,100,000 per cubic millimeter, hemoglobin 60 per cent (8.4 Gm.), and leukocytes 11,600 per cubic millimeter. The differential count was filamented polymorphonuclear leukocytes 57 per cent and nonfilamented 19 per cent, lymphocytes 21 per cent and monocytes 2 per cent. The bleeding time was five minutes and the platelets were 110,000 per cubic millimeter. A specimen of blood clotted in ten minutes (method of Lee and White) and showed a volume of 33 cc. of packed cells per hundred cubic centimeters of whole blood. The mean corpuscular volume was 100 cubic microns, the volume index 1.14 and the color index 0.9. The basal metabolic rate was 36.5 per cent plus. The rose bengal test of liver function showed a retention of 62 per cent of dye at eight minutes and 44 per cent at sixteen minutes. The icterus index was 6.

Course of Illness.—The patient entered the University of California Hospital, where, following dilation and curettage and the implantation of radium in the uterus there was a cessation of vaginal bleeding. Six months later she was examined in the outpatient department. On this occasion the liver was still enlarged. Examination of the blood showed 80 per cent hemoglobin (11.2 Gm.) and 3,450,000 erythrocytes per cubic millimeter. The icterus index was 7. The rose bengal test of liver function showed retention of 64 per cent of dye at eight minutes and 48 per cent at sixteen minutes.

There are many conflicting statements in the medical literature relative to the value of drugs used to determine the excretory function of the kidneys. The test most commonly used was described by Rowntree and Geraghty¹ in 1910 and depends on the ability of the kidneys to remove the dye phenolsulfonphthalein from the blood stream over a period of two hours. There is little doubt that the failure of the kidneys to remove the dye gives evidence of their impaired function, but there is considerable doubt as to the value of a single test in determining prognosis. Christian and O'Hara¹⁷ were of the opinion that the two hour test gave little or no evidence of early stages of renal disease. Chapman and Halsted¹⁸ believed that the test could be made more sensitive by examining specimens of urine at intervals of fifteen minutes instead of two specimens at hourly intervals. Recently MacKay and Rytand¹⁹ reported the phenolsulfonphthalein test as being of more value

in determining renal function than the estimation of urea clearance or the tests for maximum specific gravity of the urine. Elliot and Nuzum²⁰ and Don²¹ concluded, from a similar study, that there was a failure of these three tests to agree closely and that whatever agreement existed between them was little more than could be expected as a chance occurrence.

It is the opinion of many investigators²² that none of the tests employed will give accurate information as to the possible duration of the disease or the probable degree of return of function. The phenolsulfonphthalein test, however, when used at monthly intervals, may offer an approximate gage of the extent of improvement in the particular function tested. It is to be emphasized that the clinical examination of the patient, the enumeration of the cellular elements, the various types of casts in the urine and the determination of the ability of the kidney to concentrate must still be regarded as of foremost importance.

Both the liver and the kidneys perform many functions concerned with metabolism. A number of so-called metabolic tests offering many practical and theoretical possibilities have been devised in an attempt to test these functions.

CHEMICALS USED TO DETERMINE FUNCTIONS OF METABOLISM

Food substances, when used for the purpose of testing a metabolic function of an organ, may in a restricted sense be considered as acting similarly to chemicals or drugs. So far as tests for metabolic functions are concerned, however, with few exceptions little has been done that is of clinical value. It is well known that the liver plays an important role in protein metabolism and that variations in plasma protein occur in association with injury to the hepatic parenchyma.²³ Bollman, Mann and Magath²⁴ have shown that total extirpation of the liver is followed by a cessation in the formation of urea and a rise in the concentration of uric acid in the tissues and body fluids. This does not occur with partial hepatectomy. The statement is made that a considerable portion of the liver must be damaged before its function in metabolism is affected materially, and this precludes the possibility of devising a test of diagnostic or prognostic value. Tests concerned with the metabolism of fat and cholesterol are equally disappointing. This subject was reviewed recently by Epstein and Greenspan²⁵ and by Snell and Magath,²⁶ and those interested are referred to these articles for further study.

One of the functions of the liver is to prevent the accumulation of excessive quantities of dextrose in the blood stream. The modified dextrose tolerance test

has been designed as a test of this function.²⁷ This test depends on the ability of the liver to maintain the blood sugar at a certain level following the administration of dextrose, insulin and water. Wever and his associates¹³ were able to show by this method, in 92 per cent of patients studied with acute hepatitis, variations in the values for blood sugar which indicated a low reserve of glycogen. This figure corresponds closely to the results obtained with the rose bengal test. In chronic hepatitis and neoplasms of the liver the tests failed to agree as closely. The galactose tolerance test²⁸ also is used as a diagnostic procedure to determine hepatic function. Similar to the dextrose tolerance test, it may be of aid during the period of maximum damage to the liver cells. However, on account of the high degree of reparative power of the liver, variations in the metabolic function may be expected to occur. The newly formed cells may participate in metabolism of glycogen and aid in maintaining a normal level of blood sugar. Therefore a test showing a normal reaction does not always exclude injury to the liver cells.

ROENTGENOGRAPHIC VISUALIZATION OF EXCRETORY FUNCTION

Cole, Copher and Graham³ first recognized the value of using iodine to halogenate phenolphthalein in order to obtain the advantage of roentgenologic examination of hepatic and cholecystic excretion and visualization of the gallbladder. This stimulated Zwick's search for an iodized compound which would be rapidly eliminated by the kidneys in sufficient concentration to permit roentgenographic study of the urinary tract. Many drugs can be used for both these purposes. For cholecystography rose bengal might be used if the required concentration were not toxic, and the bromiodophenolphthaleins might be studied. But practically only two tetraiodo derivatives are used, soluble iodophthalein U. S. P., in which the iodine is attached to the phenol rings, and phentetiothalein sodium N. N. R., in which the iodine is attached to the phthalein radicle.

As reflected in the comments of the Council on Pharmacy and Chemistry on phentetiothalein sodium N. N. R., clinical opinion favors this drug rather than the pharmacopeial soluble iodophthalein for visualization of the gallbladder and simultaneous test of hepatic function. It is claimed to be better tolerated and more efficient. However, its use is contraindicated in uremia or myocardial insufficiency, and caution is enjoined in jaundice. The technic of administration is fully explained in New and Nonofficial Remedies.

For roentgenography of the urinary tract, the Council has approved four of the many proposed for inclusion in New and Nonofficial Remedies: diodrast, hippuran, neo-iopax and skiodan.

For urography, diodrast N. N. R. has become very popular, probably because the relatively small amount necessary to give the required concentration for effectiveness reduces the cost in comparison with similar agents. But untoward reactions occur only too frequently. These are nausea, vomiting, flushing, eruptions of the skin, dyspnea and cyanosis. The drug also causes a considerable fall in blood pressure. Dehydration and fasting of a patient before the compound

is injected is recommended as a way to reduce the severity of its effects. It is contraindicated in disorders of the liver, nephritis, uremia, tuberculosis and hyperthyroidism. Recently Robb²⁰ has used this drug for roentgenologic examination of the heart chambers following rapid injection into the cephalic vein.

Zwick's extensive survey of compounds suitable for urography led finally to a choice of sodium orthiodohippurate (hippuran N. N. R.) as the one closest to the ideal. It is less toxic than other similar agents, and may even be administered orally. Neo-iopax N. N. R., a diiodopyrodine derivative like diodrast, produces local irritation and other reactions at the site of injection. It produces untoward systemic effects similar to diodrast.

CONCLUSION

Drugs are usually considered to be related solely to therapeutics. Knowledge of the action of chemicals on living things, however, may also be applied to many diagnostic problems in medicine. If such application is made, the chemical used for a diagnostic purpose should be treated as a drug quite in the same manner as when its pharmacologic action is applied in therapy. In the diagnostic use of drugs, as when they are employed for treatment, the total physiologic action of the chemical agent must be kept in mind. A most important consideration is that the physician should carefully weigh the possible hazard from the use of the drug against the value of the knowledge he might gain by giving it.

Among the general physiologic actions of drugs which the wise physician will consider in using drugs for diagnostic purposes are local actions at the point of administration, relative rates of absorption and excretion, the fate of the chemical in the body and its mode of excretion, possible systemic reactions and untoward effects, and the relation of dosage to these effects.

ABSTRACT OF DISCUSSION

DR. FRANK NUZUM, Santa Barbara, Calif.: The review we have just heard was most impressive. I am reminded of the statement attributed to Dr. P. J. Hanzlik, that it is a good plan for the pharmacologist to prove the action of a chemical before practicing physicians use such a substance for new test material. It is my understanding that these various drugs and tests as outlined by the speakers have been carefully worked out and can be safely used by medical men. Regarding kidney function tests, I think that some medical men have the notion that the phenolsulfonphthalein and other tests are very accurate. It has come to be known that these tests are not extremely accurate and that a great deal of kidney damage must result before the present tests give evidence of such change. Recently the Goldblatt work, which has attracted so much attention throughout the country, has emphasized that the kidneys in experimental animals can be damaged to a very appreciable degree before our present clinical tests show much change. It has been assumed by experimental workers that the hypertension produced in animals by the Goldblatt plan is comparable to essential hypertension in man. Further work is needed to prove this. Kidney function tests in the Goldblatt animals may show little change, when, as a matter of fact, the kidney is badly damaged. If groups of human beings with hypertension are given three standard kidney function tests, the phenolsulfonphthalein, the Volhard and the urea clearance, there will be a 10 per cent less efficient kidney so far as these tests are concerned as compared with groups of normal individuals and compared decade by decade. While we do get a 10 per cent less efficient renal response by the kidneys in persons with essential hypertension, conclusions

cannot be accurately drawn. These tests are undoubtedly not sensitive enough to indicate the degree of change that has actually taken place.

RUSSELL L. HADEN, Cleveland: This paper had to do with the use of drugs, but it concerned particularly the study of vital functions. We have been much interested in our clinic in studying liver functions, in seeing what we could determine from the variation in the shape and size of the red cell as an index of damage to the liver. And by running quite a large series of comparative experiments we have found that the one most common thing that happens, when the liver is damaged, is that there is a change in the size and shape of the red cell; that, if one gets an obstructive jaundice, what happens to the red cell is that it flattens out without much change in volume. So there is an increased diameter with normal volume. But when there is a parenchymatous involvement of the liver, one gets uniformly an increase in the size of the cell.

DISEASE OF BILIARY TRACT ASSOCIATED WITH DISTURBANCES IN CHOLESTEROL METABOLISM

JOHN RUSSELL TWISS, M.D.

AND

JAMES H. BARNARD, M.D.

NEW YORK

This paper reports the results of treatment with the low cholesterol diet previously described by Twiss and Greene.¹ One hundred cases of disease of the gallbladder associated with hypercholesteremia were studied. Eighty of the patients were treated medically with the low cholesterol diet; a control group of twenty-one patients with hypercholesteremia did not receive the low cholesterol diet. Twenty surgical patients with hypercholesteremia before operation received the low cholesterol diet after cholecystectomy; for control purposes there were fourteen similar surgical patients who did not have the low cholesterol diet. A further investigation was made of twelve cases in which hypercholesteremia developed only after cholecystectomy.

The principles of treatment (as described at the 1932 session of the American Medical Association) included the establishment of three types of diet designed to fit the needs of the patient with disease of the gallbladder. These needs were determined by a careful initial diagnostic work-up. An original description of these diets and their use was published by Twiss and Greene;¹ a revision of the diets and the indications for their use were described in full by Bridges.²

Disturbances in cholesterol metabolism, although generally conceded to be a major contributing cause in the formation of gallstones, are as yet little understood phenomena. Comprehensive studies and reviews of the literature have been made, however, by Rolleston and McNee,³ Muller,⁴ Gardner and Gainsborough,⁵

From the departments of medicine and surgery of the New York Post-Graduate Hospital.

Schönheimer,⁶ Joslin,⁷ Hurxthal,⁸ Rehfuß and Nelson⁹ and others. Cholesterol is a secondary alcohol which is present in all cells of the body and is of great practical importance as the chief constituent of gallstones. Its source is both endogenous and exogenous, the endogenous portion being derived from the normal synthesis within the body as well as from the destruction of tissues and red blood cells. Another possible source may be the endocrine glands, such as the adrenals and the ovaries. The exogenous part comes from foods high in cholesterol of animal origin, to be discussed later. The cholesterol is probably absorbed from the intestinal tract in the form of free cholesterol and esterified in the wall of the intestine, according to Sperry.¹⁰ The cholesterol esters and free cholesterol are carried by the portal vein to the liver. Here the cholesterol is deesterized and excreted in the bile as free cholesterol, to be concentrated in the gallbladder and excreted in the bile into the intestinal tract. The greater part of this cholesterol is probably reabsorbed.

In discussing the relationship of cholesterol metabolism to the biliary tract, it is necessary first to recognize the fact that disturbances in cholesterol metabolism may be due to causes not related in that tract; hypercholesteremia may be present with diabetes mellitus, xanthoma, nephrosis, uremia, hypothyroidism, menstruation and pregnancy. Aschoff¹¹ has emphasized the importance of hypercholesteremia resulting from starvation and rapid loss of weight. The opposite condition of hypocholesteremia may occur with hyperthyroidism, acute infections, tuberculosis, pernicious anemia, primary degenerative disease of the liver, chronic toxic hepatitis and cardiac decompensation. It has been reported by Rothschild and Wilensky¹² as following the use of diets low in cholesterol.

In the biliary tract itself the most extreme degrees of hypercholesteremia are found with acute obstructive jaundice. The condition may be found to a lesser degree with chronic cholecystitis or functional disorders of the biliary tract with or without stone. Hypocholesteremia is sometimes found with starvation and with severe parenchymatous disease of the liver, which is frequently associated with conditions such as diabetes.

The dietary treatment of disease of the biliary tract associated with hypercholesteremia, as previously outlined, was based primarily on a twofold hypothesis: (a) that hypercholesteremia may result from the excessive ingestion of foods high in cholesterol and fats and (b) that a reduction of cholesterol intake by patients having hypercholesteremia causes a decrease in the amount of cholesterol in the blood. The experimental and clinical reports on both these subjects are conflicting and subject to differences of opinion in interpretation. The clinical improvement which we found to follow the use of the low cholesterol diets, however, seemed to justify further investigation as to their effect on the cholesterol level of the blood serum. The

factor of endogenous cholesterol formation may be regarded as of secondary importance in this study, as demonstrated by Rehfuß and Nelson,⁹ Chauffard,¹³ Leuret and Dutrenit¹⁴ and other investigators.

The level of the cholesterol in the blood is usually considered to be regulated by the liver. The cholesterol content of the bile is usually dependent on the cholesterol content of the circulating blood in the absence of such factors as obstruction, as shown by McNee,¹⁵ Chauffard,¹³ and Gardner.¹⁶ These investigators concluded that the cholesterol in the bile is derived directly from the blood serum and is a true excretion of the liver. Aschoff¹¹ stated that "there is a certain dependency of the cholesterol content of the bile upon that of the blood," while Rolleston and McNee³ expressed the opinion that circumstances which increase the cholesterol content of the blood plasma lead to a corresponding increase in the bile. Rehfuß and Nelson⁹ concluded: "We believe this fact is generally acknowledged by clinicians throughout the world and it forms a basis for a further study of this very important problem."

While the authorities quoted have stated that there is a definite relationship between the cholesterol levels of the bile and the blood serum, it should be added that other investigators have not been convinced of this relationship. It is not within the scope of the present report to include the numerous observations

Cholesterol Content of the Blood and of the Concentrated Gall Bile Obtained by Drainage of Patients With and Without Hypercholesteremia

	Blood, Mg. per 100 Cc.*	Bile, Mg., per 100 Cc.*
Hypercholesteremia (30 patients)...	239	59
Controls (12 patients).....	175	38
	64	21
Increase in cholesterol content in hypercholesteremic patients.....	36%	55%

* The figures are averages.

and opinions in this regard. We have nevertheless investigated the cholesterol content of the concentrated gallbladder bile (or B bile of Lyon) obtained by the duodenal drainage tube from thirty patients with hypercholesteremia. The same determinations were made for a similar series of twelve patients who did not have hypercholesteremia. As shown in the accompanying table, there was an apparent comparable increase in the cholesterol content of the concentrated bile in the cases of hypercholesteremia. Cholesterol determinations were also made on the bile removed from the gallbladder at operation for a series of patients with and without hypercholesteremia. The results, however, were in both instances so extremely variable that no definite conclusions could be based on them.

The various points of view with regard to the relationship of the cholesterol and bile salts of the gallbladder bile have been reviewed in detail by Twiss and

Greene.¹ Briefly it may be stated that a relative increase in the cholesterol concentration of the gallbladder bile, particularly in the presence of infection or stasis, may result in the precipitation of cholesterol and the formation of stones. That infection is not essential to the formation of stones, however, has been emphasized by Sweet,¹⁷ Rovsing,¹⁸ Aschoff¹¹ and others. Metabolic disturbances associated with hypercholesteremia which result in an increased excretion of

intake was followed by an average drop in cholesterol of from 360 to 208 mg. per hundred cubic centimeters of blood. Other factors, however, which must here be taken into consideration are the improvement in the diabetic condition and the effect of an increased carbohydrate intake.

The relationship of menstruation to variations in blood cholesterol is of particular interest in view of the high proportion of females in this series of patients. An increase in blood cholesterol during menstrual periods has been shown to exist by Leuret and Dutrenit,¹¹ as well as Okey and Stewart.²¹ The known elevation of blood cholesterol following experimental destruction of blood affords interesting speculation as to a possible relationship.

The work on which the present report is based was done in the biliary tract clinic of the New York Post-Graduate Hospital under the direction of Dr. R. Franklin Carter. The diagnostic work-up in each case included a determination under standard fasting conditions of the blood cholesterol, the icterus index and the van den Bergh reactions, as well as a history taking, physical examination, a cholecystogram and drainage of the biliary tract. Only those patients were included in this series who showed relative hypercholesteremia, having an initial blood cholesterol content of over 200 mg. per hundred cubic centimeters. Diabetes and kidney disease were ruled out by determinations of the sugar and urea nitrogen in the blood in practically all cases. Patients having jaundice or obstruction of the common duct were eliminated by exclusion of all patients having an elevation in the icterus index. Determinations of the basal metabolism were made for all patients suspected of having glandular dysfunction, those having an abnormal rate being omitted from the study.

With the medical patients, the follow-up studies included a detailed interval history and repeated drainage of the biliary tract in addition to periodic determi-

Fig. 1.—Statistics for 101 medical patients with hypercholesteremia treated with and without the low cholesterol diet.

cholesterol in the bile seem apt to result in the formation of stones, particularly when there is biliary stasis.

The effect of cholecystectomy on cholesterol metabolism has received but little study. Sweet¹⁷ has shown that in the dog removal of the normal gallbladder results in a transient hypercholesteremia of about forty days' duration, the blood cholesterol at times being double the preoperative amount. It is generally considered that bile is the essential factor in the emulsification and digestion of fats. Pribram,¹⁹ however, found experimentally that the essential element in the digestion of fats is not the bile but a secretion of the wall of the gallbladder. The confirmation of this finding would seem to afford a basis for further clinical studies. He said: "Patients are common who have undergone a removal of the gallbladder for biliary lithiasis who are very well for two or three years. Then, generally, after a too fatty meal or other fault in diet, a hepatic crisis occurs with congestion of the liver, epigastric pressure, intolerance of foods, the development of a hepatitis. After this accident there is a tendency to permanent and repeated relapses." The use of a diet low in fats is advised to prevent this condition.

A discussion of the use of the low cholesterol diet demands recognition of the fact that the ingestion of fats as well as foods high in cholesterol increases the blood cholesterol. Bloor²⁰ found that the feeding of fats to carnivorous and omnivorous animals results in an increase of the blood fats and cholesterol, a much greater increase resulting with herbivorous animals, such as the rabbit. The same author stressed the variability in values of the blood cholesterol, which are greater with a high fat diet and lower with a limited fat intake. The clinical application of these facts has been demonstrated by Joslin,⁷ who found in the study of a series of diabetic persons that a lowered fat

Fig. 2.—Statistics for forty-four surgical patients with hypercholesteremia treated after cholecystectomy with and without the low cholesterol diet.

nations of the blood cholesterol. With patients coming to operation, specimens of bile were obtained from the gallbladder after its removal; these were analyzed for cholesterol and bile salts, the biliary sediment was examined microscopically and bacteriologic cultures were made. The follow-up study of the medical and surgical cases was similar. The determinations of the cholesterol content of the blood and bile were made according to Sackett's modification of Bloor's method.²²

Since the increased ingestion of fats results in an increase in blood cholesterol, foods high in fats were restricted in the low cholesterol diets. The foods highest in cholesterol, as originally listed by Twiss and Greene,¹ include brain, egg yolk, fish roe, kidneys, liver, sweetbreads, butter, fatty fish and lard. The foods highest in fats, according to Bridges,² are avocado, bacon, butter, catfish, caviar, cheese, chocolate, cocoa, cream, egg yolk, meat fats and fried foods.

Fig. 3.—Observations on thirty surgical patients treated with a low cholesterol diet after cholecystectomy.

Our experience having confirmed the opinion of Pribram¹⁹ that clinically butter and olive oil are the fats best tolerated and animal fats the least well tolerated, butter in moderate amounts is the only fat we permit in the low cholesterol diets.

When there has been no satisfactory reduction in the blood cholesterol after the prescription of a low cholesterol diet, we have frequently found that the diet has not been observed. Consequently we ask the patient at every visit whether the diet has been followed. The most satisfactory results both in reduction of the blood cholesterol and in relief of symptoms have been found when intelligence and cooperation with the physician have been evident.

An analysis of the 110 medical and surgical cases of hypercholesteremia in which treatment was with the low cholesterol diet indicates that this condition is far more prevalent in women than in men. In the medical group there were twenty-one males and eighty-one females and in the surgical group four males and forty females. The average age varied from 39 to 42 years.

Of the eighty medical patients with hypercholesteremia who were treated with the low cholesterol diet, sixty-five, or 81 per cent, showed an average reduction in blood cholesterol of 19 per cent. The average initial value for blood cholesterol was 262 mg. per hundred cubic centimeters, and the average final value, 211 mg., showing a reduction after treatment of 51 mg., or 19 per cent (fig. 1). In the control group of twenty-one patients having hypercholesteremia, who were not treated with the low cholesterol diet, half showed a reduction in blood cholesterol. The average reduction, however, was only 12 mg., or 5 per cent (fig. 1).

With regard to the clinical results of treatment in the eighty patients who received the low cholesterol diet, 29 per cent were symptom free, 51 per cent improved and 20 per cent unimproved. Of those who were unimproved, 5 per cent were found to have stones. In some cases operation had been refused; in others operation was subsequently performed. This leaves an unexplained 15 per cent in whom there was no symptomatic improvement. In the control series of twenty-one patients who did not receive the low cholesterol diet, only 14 per cent were symptom free,

19 per cent were improved and 67 per cent were unimproved. Of those unimproved, 23 per cent had stones, leaving a balance of 44 per cent for whose lack of improvement there was no apparent reason aside from the fact that they had had no dietary management.

The thirty surgical patients treated with the low cholesterol diet after operation were found to have an average initial value for blood cholesterol of 238 mg. per hundred cubic centimeters before cholecystectomy. Of these, twenty, or 67 per cent, showed an improvement in the level of the cholesterol, the average decrease being 58 mg., or 24 per cent (chart 2). A control series of fourteen patients with hypercholesteremia pre-operatively were not given the low cholesterol diet after operation. In this series 64 per cent showed a reduction in blood cholesterol after operation. The average decrease was 20 mg., or 9 per cent, approximately only a third of that in the series of patients on the low cholesterol diet.

Clinical observation of the thirty patients who were given the low cholesterol diet after operation showed 46 per cent symptom free, 33 per cent improved and 21 per cent unimproved. In the control series of fourteen patients who did not have the low cholesterol diet, 43 per cent were symptom free, 21 per cent improved and 36 per cent unimproved (chart 2). Since the clinical results in the two groups of surgical cases are somewhat inconclusive, a further study was made of the symptomatic response to the low cholesterol diet on the basis of reduction in blood cholesterol. Of the twenty patients showing a reduction in blood cholesterol, 45 per cent were symptom free, 45 per cent improved and 10 per cent unimproved. On the other hand, of the ten having no reduction in blood cholesterol only 60 per cent were improved, 40 per cent showing no clinical improvement (chart 3).

Fig. 4.—Intervals in which minimum values for blood cholesterol were obtained with a low cholesterol diet in medical and postoperative cases.

Another phase of this investigation was concerned with the interval from the institution of the low cholesterol diet until the minimum value for blood cholesterol was obtained. The maximum reduction in blood cholesterol occurred in 63 per cent of the medical cases during the first four months, in an additional 30 per cent in the next four months and in only 7 per cent after the eighth month. In contrast to this, in the surgical cases, in which the low cholesterol diet was started after cholecystectomy, the maximum reduction in blood cholesterol occurred in 40 per cent during the first four months, in 10 per cent during the next four months and in 50 per cent after the eighth month

(chart 4). Thus it is obvious that with regard to the hypercholesteremia the response to the low cholesterol diet is in most medical cases prompt, whereas after surgical intervention the response may be greatly delayed.

For further evidence of the importance of the low cholesterol diet after cholecystectomy we studied an additional series of twelve patients who had a normal value for blood cholesterol preoperatively but who had hypercholesteremia after operation. In this group the average preoperative value for blood cholesterol was 172 mg. per hundred cubic centimeters and the average maximum postoperative value 239 mg. The maximum increase in blood cholesterol occurred in half the cases within the first four months after operation; in most of the remainder, however, the maximum values were obtained after the eighth month. These observations seem to indicate the advisability of restricting the intake of fats and foods high in cholesterol for an indefinite period after cholecystectomy. The association of hypercholesteremia with symptoms following operation has previously been noted.

SUMMARY

1. A series of 110 medical and surgical patients with disease of the gallbladder and associated hypercholesteremia were treated with a low cholesterol diet. A control series of thirty-five patients did not receive this diet.

2. Of eighty medical patients 82 per cent showed an appreciable reduction in blood cholesterol; 80 per cent were symptomatically improved. Fifty per cent of the control group showed an inconsequential reduction of blood cholesterol; 33 per cent were symptomatically improved.

3. Sixty-seven per cent of the thirty surgical patients treated with the low cholesterol diet after cholecystectomy showed an average reduction in blood cholesterol of 24 per cent; 79 per cent were symptomatically improved. In the control group 65 per cent of the patients showed an average reduction in blood cholesterol of 5 per cent and 64 per cent showed symptomatic improvement.

4. Of the surgical patients who had symptoms after cholecystectomy and were treated with the low cholesterol diet, 10 per cent of those showing a reduction in blood cholesterol were unimproved. In the control group 40 per cent were unimproved.

5. Minimum readings of the blood cholesterol were obtained within the first eight months for 93 per cent of the medical patients on the low cholesterol diet, whereas after cholecystectomy minimum figures were obtained only after eight months for 50 per cent of the patients.

6. Twelve patients with gallbladder disease who had a normal value for blood cholesterol preoperatively had hypercholesteremia after cholecystectomy.

CONCLUSIONS

1. The low cholesterol diet has been found by repeated chemical analyses to reduce the blood cholesterol in cases of hypercholesteremia.

2. The low cholesterol diet gives symptomatic relief in most of these cases.

3. The diet is indicated also after cholecystectomy to preclude hypercholesteremia and recurrent symptoms.

ABSTRACT OF DISCUSSION

DR. ARTHUR L. BLOOMFIELD, San Francisco: I find the paper of Dr. Twiss and Dr. Barnard interesting but difficult to discuss, because I am not entirely sure what kind of diseases they are talking about. That is true with many diseases or disorders pertaining to the biliary tract and to the gastrointestinal tract. If several physicians talk about auricular fibrillation they all know that they are dealing with exactly the same thing; but with the gallbladder, beyond biliary colic and obvious more or less acute infections, there is room for a difference of opinion as to diagnosis. It may be that some of the patients whom the authors have referred to would by others be regarded as having had some functional disorder. It is conceivable that a regimen of any sort plus psychotherapy might have led to relief of symptoms. I raise this possibility, which probably the authors will demolish, because it is difficult for me to see why reducing the cholesterol content, if that is what happens, should so promptly do away with the somewhat miscellaneous group of symptoms. I can see that if cholesterol in the bile could be reduced over a long period there might be less tendency for cholesterol to be deposited in the wall of the gallbladder or for gallstones to develop, but it is difficult for me to see why the patient should so promptly be improved. I seek to find some other explanation, and I should like to hear a more definite interpretation as to the mechanism whereby the patient is promptly relieved of his symptoms by this diet.

DR. JOHN RUSSELL TWISS, New York: In answer to Dr. Bloomfield's first question, as to why the patient shows such prompt relief of symptoms after being put on this diet, I made no statement to that effect. What I said was that the reduction in blood cholesterol occurred in 63 per cent of the patients within the first four months. I said nothing about the time required for the symptoms to disappear. However, I will say that the majority of the patients did show symptomatic relief within four months. Dr. Bloomfield would like to know on what basis we made our diagnosis. We make our diagnosis of gallbladder disease on the symptoms. The symptoms which we have found most commonly associated with such disease are those of "indigestion," by which we mean belching, distention, fear of eating, discomfort after meals, in some cases nausea and vomiting and in some cases colic and jaundice, the last-mentioned symptoms being relatively uncommon. Our second criterion for diagnosis is the appearance in roentgenograms. We made roentgenograms in every one of the cases reported. The indications of gallbladder disease were impaired visualization of the gallbladder, delayed emptying of the gallbladder, lack of visualization of the gallbladder or the presence of stones. Dr. Bloomfield would like to know why we said that the patients had gallbladder disease. In addition to the considerations previously mentioned, we had drained the biliary tract in every case. We had repeatedly examined the biliary sediment microscopically according to the method of Lyon. Furthermore, we had made bacteriologic examinations of the bile in a large proportion of cases, not only by drainage but at the time of operation. Our diagnostic criteria also included the chemical examination of the blood previously mentioned, especially the determination of the icterus index. We feel that the icterus index is a very important test, and we find that in a great many questionable cases a moderate elevation of the index, a reading between 8 and 15 (in the so-called zone of latent jaundice), is an important additional factor in making a diagnosis of disease of the gallbladder.

Number of Public Institutions for Feeble-minded.—

According to the latest available figures, there are now in the United States seventy-six public institutions for the feeble-minded (or for both the feeble-minded and the epileptic) with a total population of about 75,000. In addition there are some 113 private establishments with a combined enrolment of little more than 2,000. Altogether, these institutions accommodate less than one fifteenth of the estimated number of mental defectives in this country. Forty-four states have state institutions for the feeble-minded.—Deutsch, Albert: *The Mentally Ill in America*. New York, Doubleday, Doran & Co., Inc., 1937.

SULFANILAMIDE AND SERUM IN THE
TREATMENT AND PROPHYLAXIS
OF SCARLET FEVER

WALLACE SAKO, M.D.; P. F. DWAN, M.D.

AND

E. S. PLATOU, M.D.

MINNEAPOLIS

In 1935 Domagk¹ showed that prontosil² had a marked protective and therapeutic value in experimental streptococcal infections in mice. This observation has been confirmed by numerous investigators. The drug also has a beneficial effect on similar infections in other animals and in man. Shortly after Domagk's discovery, Tréfouël and his co-workers³ showed that prontosil was broken down in the tissues to triaminobenzene and para-aminobenzene sulfonamide. The latter compound was believed by them to be the effective component of prontosil. Recently numerous derivatives of the drug have been synthesized, but the estimation of the effectiveness of many of them requires further investigation.

The mode of action of sulfanilamide and its derivatives is still the subject of much conjecture. Since prontosil has little or no bactericidal action in vitro, Domagk believed that enhancement of phagocytosis of the streptococci by the leukocytes explained its beneficial effect. Levaditi and Vaisman⁴ "advanced the theory that this drug interfered with capsule formation, thus rendering the streptococci susceptible to phagocytosis." This view was later questioned by the experiments of Long and Bliss.⁵ Harleiss⁶ and Schranz⁷ speculated that an activation of the reticulo-endothelial system was the important action of the drug. Long and Bliss stated that sulfanilamide was not bactericidal in vitro. They were unable to confirm Colebrook and Kenny's⁸ claim that the serums of patients treated with sulfanilamide exerted a bactericidal effect on beta hemolytic streptococci in vitro. In experimental streptococcal and Welch bacillus infections they further concluded that bacteriostasis is the main effect produced by sulfanilamide therapy. On the basis of ingenious experiments with cultures taken from bone marrow, Osgood⁹ concluded that neutralization of toxins by sulfanilamide played the major role and bacteriostasis was of secondary importance.

The favorable clinical results obtained with sulfanilamide in treating hemolytic streptococcus infections make it logical to assume that similar effects might be expected from the use of this drug in the treatment of scarlet fever. The only report in the literature which seems to indicate that it is of value is by Peters

and Havard,¹⁰ who used para-benzyl-aminobenzene-sulfonamide (proseptasine) and found that the incidence of complications dropped appreciably after the administration of the drug to patients with scarlet fever.

We have attempted to compare a series of 100 scarlet fever patients treated with sulfanilamide during 1937-1938 with an equal number of controls who did not receive the drug. The two series, although not composed of alternate cases, ran concurrently and were comparable with respect to age, severity and duration of disease prior to treatment. Although the criteria for evaluating our results may be subject to criticism, some observations have been made which we believe are significant and seem to suggest that sulfanilamide is of value in the treatment of scarlet fever.

The drug was administered orally except to patients with nausea or extreme toxemia. The latter were given an initial large dose subcutaneously in the form of 1 per cent solution in physiologic solution of sodium chloride. The dosage used was that recommended by Long and Bliss¹¹ for severe infections: an initial massive dose of 0.05 Gm. per pound of body weight and a maintenance dose of 0.03 Gm. per pound in twenty-four hours. It is our impression that, per unit of weight, children tolerate the drug better than adults. With the exception of the development of leukopenia in two cases and a fever and rash in two additional cases in which we were compelled to discontinue therapy, no serious complications were encountered with the drug. Cyanosis without sulfhemoglobinemia was observed in several instances but therapy was continued without any ill effects. The dosage was gradually decreased but was continued on an average of twelve days. Too early discontinuance of the drug was believed to be the cause of the appearance of mild complications in a few of our cases. The best results were obtained when sulfanilamide was continued during the entire convalescent period. The fever curve in the treated cases, once it became normal, remained so in practically all cases without complications, whereas the untreated cases showed irregular rise in temperature, often without demonstrable explanation for this rise.

Tables 1 and 2 illustrate the most significant observations in our comparison between sulfanilamide treated and control cases. The incidence of complications was 41 per cent in the controls as compared to 8 per cent in the treated cases. As will be noted, there were nine suppurative conditions in the control cases as compared to one in the treated series.

In our treated cases the rate of recovery from the acute toxic phase of the disease (six days) was no more rapid than it was in the control cases (six days). The patients treated with sulfanilamide did not show the prompt subsidence of toxic symptoms such as we have observed following the administration of serum.

SERUM THERAPY IN SCARLET FEVER

During the past decade an abundance of literature has accumulated concerning the beneficial influence of commercial antitoxin and human convalescent serum on toxemia, temperature, rash and complications of scarlet fever. Differences of opinion apparently still exist as to the degree and character of action of these serums.

Some investigators contend that they are both purely antitoxic, whereas others believe that human convalescent serum has antibacterial properties as well.

Rhoads and Gasul¹² have shown by titration methods that twelve lots of pooled convalescent serum contained an average potency of only 500 neutralizing units of antitoxin per cubic centimeter as compared to 15,000 units per cubic centimeter in commercial antitoxin. It is obvious, therefore, that the antitoxic potency of

Total	8

convalescent serum was found to be only one thirtieth that of the commercial product.

In spite of this relatively low antitoxic titer of convalescent serum, the clinical results reported by Thalhimer, Hoyne and Levinson¹³ and others following therapeutic doses of 40 cc. compared favorably with those reported by one of us¹⁴ at about the same time, commercial antitoxin being used in doses fifteen times as large when expressed in antitoxic neutralizing units.

The two groups of cases listed in table 4 contain about the same percentage of severe types and were observed at the same time in nearby midwestern cities, although they are not identical samples. The roughly similar reduction of principal complications in the two series as compared to controls suggests the possibility that factors other than antitoxic titer may explain the results obtained with human convalescent serum.

Although massive doses of convalescent serum are required to match the antitoxic titer of commercial antitoxin, it is believed by some that such quantities of human serum are clinically much more effective than an equivalent amount of commercial antitoxin. This is offered as further evidence that convalescent serum is to some extent antibacterial, or at least that its beneficial effect is not limited to its specific antitoxic content. Our own experience with massive doses of convalescent serum in critically ill patients suggests that this is true.

Observers consistently emphasize the importance of early administration of serum, some stressing the quantitative factor in therapy, but too few have dwelt on the need for a safe, rapid dissemination of antibodies which specifically combat the peculiarly widespread toxemia seen in scarlet fever. Human convalescent serum has a great advantage over horse serum with respect to safety when either is to be used intravenously, and this method of administration would certainly seem the logical one to follow in treating this disease.

If sulfanilamide eventually justifies the promise it now gives of being adequate in the average case of scarlet fever, it will perhaps be more than ever true that serum should be reserved as an adjunct for the severe cases in which its help is especially desired.

PROPHYLAXIS

Essential factors determining the variability of scarlet fever are the virulence and dosage of the organisms and the resistance of the host. Epidemiologists believe that virulence is probably the least variable of these factors, and, since infectious dosage cannot be controlled, success in prophylaxis against scarlet fever must necessarily depend on one's ability to increase host resistance.

Experimental evidence suggests that small doses of convalescent serum may modify the permeability of cells and prevent the intimate parasitism usually exhibited in virus diseases. In bacterial disease, however, such a phenomenon is probably not operative, and in order to effect prophylaxis one must rely on increasing antitoxic or antibacterial properties of the blood.

It has been shown that scarlet fever convalescent serum and commercial antitoxin in large doses neutralize toxin and therefore are useful in the treatment of the disease. However, if scarlet fever convalescent serum contains quantitatively only small amounts of antibacterial substance, it follows that one must depend for prophylaxis principally on raising the antitoxic levels of the blood.

Does convalescent serum in 20 cc. dosage contain sufficient antitoxin to alter materially host resistance? If Rhoads and Gasul's titration values of 500 neutralizing units per cubic centimeter are correct, it would mean that in 20 cc. of serum only 10,000 neutralizing units is added in the attempted change of antitoxic status. These observers found that a large proportion of twenty Dick positive persons who had received from 10 to 20 cc. of convalescent serum had not become Dick negative several days later. If antitoxin alone is to be used as a criterion for immunity, it would seem from this evidence that susceptibility may not be as greatly modified by 20 cc. of serum as would be desired.

Will 20 cc. of convalescent serum prevent invasion of the body by the scarlet fever streptococcus? One

of us (E. S. P.) witnessed failure to prevent such invasion in five of ten children (from 12 to 16 years of age), each of whom received 20 cc. of pooled scarlet fever convalescent serum. The five who did not contract the disease received additional chemotherapy with sulfanilamide.

One of a group of eleven English choir boys touring this country contracted scarlet fever while in Chicago. He was immediately removed to a municipal contagious hospital and the ten remaining boys were given

20 cc. each of pooled convalescent scarlet fever serum from the Samuel Deutsche Serum Center. The subsequent course of these cases seems interesting enough to warrant detailed description.

After seven days of isolation, the ten boys were permitted to proceed to Madison, Wis., where on the eighth day after receiving serum J. C. (patient 1) was sent to a hospital with scarlet fever. On arriving in Minneapolis ten days after administration of the serum,

TABLE 3.—Principal Complications in Cases Treated with Human Convalescent Serum as Compared to Controls

983 Treated Cases	6,282 Controls
9.5%.....Lymphadenitis	27.0%
8.8%.....Purulent otitis media.....	13.6%
0.2%.....Hemorrhagic nephritis	3.6%
18.5%.....Total	44.2%

G. P. (patient 2), was taken severely ill with angina, hyperpyrexia and prostration. Because cultures taken on material from the throat showed the presence of hemolytic streptococci, he was quarantined in the Minneapolis General Hospital. A very faint erythema appeared in the axillas at the end of forty-eight hours. During his stay in the hospital, otitis media, cervical adenitis, a mild nephritis and desquamation developed.

The day after the admission of patient 2 to the hospital (eleven days after serum administration), A. C. (patient 3), who gave a history of sore throat and fever three days after administration of serum, had a typical postscarlet tongue and slight desquamation and remained culture positive during three weeks of quarantine. This boy gave no history of previous scarlet fever and is now Dick negative. K. S. (patient 4) had a sore throat and fever the same day that patient 3 was isolated but recovered promptly without a rash or complications developing and was released under observation with two negative cultures at the end of one week.

J. S. (patient 5) was taken ill with a sore throat and had a positive culture the same day as patient 4, and although no rash developed his tongue gradually assumed a "strawberry" appearance, his temperature rose intermittently to 105 F. and nephritis, renal abscess, multiple arthritis and endocarditis developed.

The remaining five boys received sulfanilamide during the ten days of isolation, and negative cultures were obtained before release. They have remained well since.

Most observers who have reported on the prophylactic merits of convalescent serum contrast the incidence of the subsequent scarlet fever complex with the average morbidity among unprotected contacts. If convalescent serum modifies the complex to the extent of preventing a rash, may it not be that erroneous conclusions on the prophylactic merits of 20 cc. of serum may result? Can one be sure that fewer cases of invasion actually result, especially when there is no previous appraisal of host resistance? Certainly frank failures with serious complications make one wonder whether 20 cc. of serum will offer much help to those most in need; namely, those who receive large bacterial dosage or those who have particularly low resistance.

Prophylactic doses of commercial antitoxin have likewise been found lacking in adequate protection against bacterial invasion. During the past several years there

have been admitted to the Minneapolis General Hospital five patients with scarlet fever who have been known to have had such prophylaxis from two to twelve days previously. Two of these patients died, one from streptococcic laryngotracheobronchitis and the other from septicemia.

CHEMOPROPHYLAXIS

Most of the experimental evidence relative to the merits of sulfanilamide indicates that it has a very definite prophylactic effect. Domagk, who first demonstrated the value of prontosil, showed that it had a protective action on mice.

The finding of a throat culture positive for hemolytic streptococcus in a susceptible child exposed to the disease in a critical form prompted one of us (E. S. P.) to try sulfanilamide for protection, and the outcome was so favorable that we have used it cautiously in sixty intimate contacts to date with no failures. This number of cases is obviously too small from which to draw any conclusions. The drug cannot be recommended for routine prophylactic use until its mode of action, optimal dosage and allergic or toxic effects are more clearly understood. It is hoped that the future may possibly offer something worth while in the use of this drug perhaps as a synergistic agent complementing the action of serum.

SUMMARY

Among 100 cases of scarlet fever treated in which large doses of sulfanilamide were given complications developed in eight whereas among 100 similar cases in which the drug was not given complications occurred in forty-one.

The rate of recovery from the acute toxic phase of the disease among the sulfanilamide treated as compared to the control cases could not be said to be accelerated.

Scarlet fever toxemia has been shown to be strikingly modified by early massive doses of antitoxin contained in human convalescent serum and commercial horse serum.

Although human convalescent serum has a lower antitoxic titer per cubic centimeter than commercial antitoxin, the former has a distinct advantage with respect to safety for intravenous use.

TABLE 4.—Principal Complications in Cases Treated with Commercial Antitoxin as Compared to Controls

1,664 Treated Cases	2,000 Controls
3.9%.....Lymphadenitis	11.7%
5.9%.....Purulent otitis media.....	12.7%
0.8%.....Hemorrhagic nephritis	3.8%
10.6%.....Total	28.2%

Twenty cc. of pooled human convalescent serum failed to prevent the streptococcic invasion of scarlet fever in five of ten boys who were intimately exposed to it, whereas the five who received additional chemoprophylaxis did not contract the disease.

Commercial antitoxin in our experience has failed to protect several persons against the streptococcic invasion of scarlet fever.

Early massive intravenous serum therapy to combat toxemia combined with continued large doses of sulfanilamide seems to be the most efficacious treatment for scarlet fever.

953 Medical Arts Building.

MEDIASTINAL INFECTION FROM ESOPHAGEAL PERFORATION

CHARLES E. PHILLIPS, M.D.

LOS ANGELES

Mediastinitis due to perforation of the esophagus has been generally considered a fatal condition.

Quotations from three representative authorities will suffice to show the expected outcome of this accident: "Rupture or perforation of the esophagus results in a mediastinal infection, which is fatal" (Broyles¹). "If, in consequence of such injury, the mediastinum or the pleura is opened, death from infection is almost certain to occur" (Torek²). "The occurrence of a perforation of the esophagus is in the vast majority of cases associated with fatal consequences" (Graham, Singer and Ballon³).

Unfortunately these statements are true, but needlessly so. The work of Chevalier Jackson, Chevalier L.

Fig. 1.—Sagittal section of the cervical and superior mediastinal spaces with narrowing of the retrovisceral space between the superior and posterior mediastinal spaces.

Jackson, William Lerche,⁴ Herman Pearse Jr.⁵ and a few others shows that a great majority of patients can be saved by surgical intervention.

I desire to present my own series of twenty cases of mediastinal infection from esophageal perforation. There were in this series three deaths, all of which under different circumstances might have been prevented.

The anatomy with which this condition is particularly concerned consists of a space surrounding the

esophagus and extending in continuity from the retropharyngeal space to the diaphragm. This space is filled with loose areolar tissue and shows two points of constriction. The first point is at the superior aperture of the thorax, where the parietal pleura is attached to the first rib. The second point of constriction is at the junction of the superior with the posterior mediastinal spaces, where the roots of the lung, bifurcation of the trachea and great vessels seem to form a partial barrier to the passage of infection. In only three of the twenty cases analyzed did infection travel from the superior to the posterior mediastinum, although infection readily passed from the retropharyngeal space to the superior mediastinum in a majority of the cases.

The periesophageal or mediastinal spaces are in constant motion from the surrounding pulsating vessels and moving pleura, rendering the presence of infection especially hazardous.

The wall of the esophagus is composed of mucous, submucous and muscular coats. The vulnerability of the esophagus to blunt force or to perforation by sharp objects is striking. After perforation has occurred, the constant motion of the mediastinal structures predisposes to a rapid dissemination of infection.

Perforations of the esophagus occur for the most part in its upper portion; first, because this is the most constricted section and the most exposed to traumatism; secondly, because ingested material changes its course as it enters the esophagus from the pharynx, and, finally, because the pharyngeal muscles compress the food from a globular to an elongated mass and push it from the pharynx into the esophagus, so that foreign bodies of dangerous dimensions mixed with the food are caused to protrude and perforate the esophagus. Once infection is liberated in the periesophageal spaces of the neck, the line of spread depends on the amount and virulence of the infective material.

When the infective material is relatively small it may remain localized in the neck for some time and then gradually descend into the superior mediastinum and along the great vessels in the base of the neck. This course of extension explains the lateral swelling of the base of the neck. The infection penetrated into the superior mediastinum in every case in which there was found a lateral swelling in the neck.

The diagnosis of mediastinal infection from esophageal perforation must be made promptly, and the abscess accurately localized to assure success in treatment. The diagnosis is made on the following points:

1. There is a history of injury following the ingestion of some sharp substance or of perforation during instrumentation.

2. Immediate symptoms of pain, tenderness and dysphagia are followed by fever, swelling and subcutaneous emphysema.

3. X-ray examination may show a foreign body, emphysema or irregularities of the tissues after the ingestion of an opaque meal.

4. Endoscopic examination may show gross perforations and suggestive irregularities or perforating foreign bodies.

It is only by the selective application of any or all of these measures that an early diagnosis can be attained.

The mechanism of infection is varied: (a) It may slowly perforate an injured mucosa and later reach the mediastinum. (b) A virulent infection with a minimum of trauma may set up active mediastinitis.

Read before the Section on Surgery, General and Abdominal, at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

Dr. Simon Jesberg referred a majority of the patients and did the endoscopic work in localizing the lesions. Dr. Alden H. Miller assisted in assembling the records.

(c) A minute perforation may remain walled off from the mediastinum until the opening into the esophagus closes and then a fulminating mediastinitis result. (d) A wide opening in the mediastinum leads to rapidly spreading emphysema and mediastinitis.

Accidents and complications due to unforeseen conditions arose in several cases of this series. The penetration of infection into the great blood vessels, resulting in septicemia, constituted the chief threat to

normal expansion and contraction of the esophagus in swallowing represents the amount of available space that can be utilized with safety in entering the mediastinum. The space will not always admit the finger without possible injury to the pleura, but it will accommodate about three Dakin tubes on each side of the esophagus without undue pressure on the pleura. The Dakin tubes, with lateral openings, are inserted into the superior mediastinum. It is essential that the tubes be kept free and open, so that they may function as drainage as well as irrigation tubes. The motion of the mediastinal structures forces out the solution soon after it is injected and disinfection of the mediastinum is effected. The irrigation should be done every two hours until the infection subsides. Thereafter it is repeated twice daily as the tubes are gradually removed. By a gradual shortening of the tubes, the mediastinal cavity is made to close from the bottom. The average acute mediastinitis clears up within ten days or two weeks and is healed completely in another week.

When the infection is in the posterior mediastinum the surgical attack should be made from the dorsum. After localization of the perforation, the resection of 2 inches of the posterior end of two ribs below the point of perforation and displacement of the pleura outward will afford access to the posterior mediastinum. It is to be well noted that the thoracic duct is exposed to injury when the left side is opened.

When the barium sulfate used for the visualization of the perforation is encountered, the Dakin tubes are placed and the wound closed to the tubes. In all cases of mediastinitis a feeding tube is passed through the nose and down the esophagus. It is left in situ until the esophagus is healed. Usually it can be discarded at the end of ten days, provided no further leakage takes place through the perforation.

CONCLUSIONS

When the perforation is recognized immediately and proper treatment instituted without delay, recovery is reasonably assured.

Fig. 3.—The superior aperture of the thorax, showing the relations of the pleura and esophagus.

Septic mediastinitis from perforation of the esophagus is a curable condition. The essentials of success are early diagnosis, the services of a skilful endoscopist and radiologist and a surgeon with the ability to use regional anesthesia and diluted solution of sodium hypochlorite. In this series early operation would have saved at least two of the three patients who died.

Fig. 2.—Retropharyngo-esophageal surfaces, showing four hypothetical foreign bodies: "a" will be swallowed safely; "b" will lodge and probably be regurgitated without damage and "c" and "d" may lead to perforation with attempts to force them down the gullet.

life. None of the patients treated within the first twenty-four hours after perforation succumbed to infection. Serious secondary hemorrhage occurred in two cases, 7 and 17. One patient recovered and the other died. Patient 7 suffered a slough of his internal jugular vein from the pressure of the Dakin tubes but recovered. Patient 17 sloughed a section of her esophagus and promptly died of hemorrhage. In case 9 the thoracic duct was injured but recovery ensued. The second death, in case 11, resulted from a double pneumothorax. The third death, in case 20, was a result of infection. The patient refused operation until two days had elapsed after perforation, and he died of spreading infection.

Surgical treatment has for its objectives:

1. Localization of the lesion.
2. Surgical approach and evacuation of the abscess.
3. Release of pressure.
4. Sterilization of the abscess cavity by diluted solution of sodium hypochlorite.
5. Continued disinfection until healing is complete.

Infection in the retropharyngeal and superior mediastinal spaces is treated by a surgical approach through an incision along the anterior border of the sternocleidomastoid muscle. The muscles are separated, and the lower pole of the thyroid is elevated. This affords an easy access to the periesophageal and the superior mediastinal spaces.

It is important that the parietal pleura be uninjured in the approach to the superior mediastinum. Perforation of the pleura usually leads to disaster. The

REPORT OF CASES

CASE 1.—Mrs. C. H. F., white, aged 40, who was admitted to the Methodist Hospital Aug. 20, 1919, complaining of pain in the throat, inability to swallow, swelling of the right supraclavicular region and symptoms of sepsis, said that four days previously, while she was eating chicken, a piece of rib had stuck in her throat. There were increasing pain and fever, and for the preceding twenty-four hours she had noticed swelling

Fig. 4.—Lower boundary of the superior mediastinum, where a descending infection is usually arrested.

of the right supraclavicular region. She called Dr. Simon Jesberg, who located a bone which was perforating the esophagus 3 inches below the hyoid bone. He removed it through the endoscope and referred the patient for surgical drainage. With the patient under general anesthesia the neck was opened through an incision along the anterior border of the right sternocleidomastoid muscle. The mediastinum was entered under the right lobe of the thyroid. An abscess was found surrounding the esophagus and extending into the superior mediastinum. Dakin tubes were inserted and irrigations carried out every two hours. The patient recovered in nine days.

CASE 2.—H. E. B., a white man aged 27, admitted to the Methodist Hospital May 22, 1923, had swallowed a fish bone a week previously. The throat was quite sore and then improved for two days, after which there was a marked increase of symptoms, with inability to swallow, fever, and tenderness of the neck. The patient consulted Dr. Jesberg, who made a careful endoscopic examination, with negative results, and referred him for surgical treatment. Cervical block anesthesia on the left side was used, and the neck was opened through an incision along the anterior border of the left sternocleidomastoid muscle. A mediastinal abscess was found and evacuated, and Dakin tubes were inserted. The postoperative course was uneventful, and the patient was discharged as cured June 13.

CASE 3.—Mrs. J. J. H., white, aged 53, admitted to the Methodist Hospital June 7, 1926, had had a bone catch in her throat about six months previously. The bone was removed, but the throat remained sore and gradually became worse. There was great difficulty in swallowing. She suffered a loss in weight of 30 pounds (13.6 Kg.). She consulted Dr. Jesberg, who made an endoscopic examination, finding an inflammatory mass obstructing the esophagus and also a tracheo-esophageal fistula. He was unable to pass the endoscope. Barium sulfate was given, and x-ray examination by Dr. W. B. Bowman showed almost total occlusion of the esophagus. The barium mixture flowed into the trachea. A preliminary gastrostomy was done with local anesthesia, and then, with the patient under general anesthesia, an incision was made along the anterior border of the left sternocleidomastoid muscle. A large abscess was found in the superior mediastinum, communicating with

the tracheo-esophageal fistula. Dakin and drainage tubes were inserted. The patient was fed through the gastrostomy opening, and Dakin's treatment was instituted, care being used on account of the tracheal fistula. The patient made a complete recovery.

CASE 4.—Mrs. L. A., white, aged 59, was admitted to the Hollywood Hospital July 29, 1928. About six weeks previously a bone had lodged in her throat and she had gone to the Ear and Eye Hospital, where Dr. Jesberg removed it through an endoscope. She was greatly improved and went home after a few days. The throat remained sore, and a few days before her admission to the Hollywood Hospital there was a sudden exacerbation of pain associated with fever, hoarseness, dysphagia and respiratory embarrassment and swelling in the left supraclavicular region. The urgency of the symptoms necessitated immediate operation. Cervical block anesthesia on the left side was used, and the superior mediastinum was opened through a left-sided collar incision. A large abscess was found extending from the neck into the superior mediastinum. Dakin tubes were inserted, and cultures were taken. These showed gram-negative bacilli and cocci. On August 6 a large slough came out, and healing followed.

CASE 5.—H. B. R., a white man aged 36, was admitted to the Eye and Ear Hospital May 12, 1932, with a history of having swallowed a chicken bone that day. Immediate endoscopic examination by Dr. Jesberg failed to show the bone. On the following day there was marked swelling of the neck and a temperature of 101 F. On May 14 operation was performed. Under regional anesthesia both sides of the neck were opened along the anterior border of the sternocleidomastoid muscle. A large rent was found in the posterior wall of the esophagus. The chicken bone was found in the prevertebral space, and the infection had penetrated into the mediastinum. Dakin tubes were inserted, and irrigations were given every two hours. The temperature remained up for six days and then subsided. The Dakin tubes were removed at the end of a week and the patient was discharged as cured after nine days.

Fig. 5.—The relations of the esophagus and mediastinal structures.

CASE 6.—M. G., an elderly, white, insane woman, while in an asylum, on March 18, 1928, broke her false teeth and attempted to swallow them. She was transferred to the Eye and Ear Hospital, where an endoscopic examination was attempted by Dr. Jesberg, but so much respiratory embarrassment resulted that the attempt was discontinued. The patient's condition remained precarious until March 30, when a mediastinotomy on the left side was performed. Much pus and barium sulfate were found. Drains and Dakin tubes were inserted, and no further exploration was attempted. On April 5 an exacerbation

of symptoms, with the temperature up to 102 F., necessitated further exploration. A foreign body was found surrounded by much necrotic material. The Dakin tubes were replaced and irrigations were resumed. The physical recovery was uneventful.

CASE 7.—A white man aged 35, on July 11, 1933, while eating had a bone stick in his throat. He entered the Eye and Ear Hospital, where Dr. Jesberg removed the bone through an

Fig. 6 (case 7).—Emphysema of the neck and a bone, indicated by arrow, in the esophagus.

endoscope. By the next morning there was such emphysema of the tissues of the neck and face that the eyes could not be opened and a usually prominent nose was represented as a dimple in the swollen face. Barium sulfate and roentgenograms showed the barium preparation in the mediastinum and the tissues filled with air (figs. 6 and 7). Under block anesthesia the mediastinum was opened through an incision along the anterior border of the right sternocleidomastoid muscle. There was so much distortion of the tissues by the emphysema that the mediastinum was opened inadvertently from the outer rather than from the mesial side of the carotid sheath. When the air escaped from the tissues, it was found that the internal jugular vein was exposed along the mesial side of the incision and was in contact with the Dakin tubes placed in the mediastinum. Dakin's treatment was carried out every two hours. On the second night the pressure of the tubes caused a rupture of the internal jugular vein. The patient coughed and lost a half pint of blood from the incision in the neck. The nurse found that pressure on the neck controlled the hemorrhage. An emergency operation with regional anesthesia was done, the internal jugular was tied and the tubes were placed through an incision made on the mesial side of the vessels on the opposite side of the neck. A transfusion of blood was necessary. The patient had a stormy convalescence but recovered within two months.

CASE 8.—R. W., a white man aged 41, swallowed a chicken bone July 4, 1934. The bone was removed through the endoscope by Dr. Jesberg July 6. Symptoms improved until July 11, when there was an increase of pain and the neck began to swell. The temperature went to 101 F. An x-ray examination July 17 showed a widening of the prevertebral space. July 19 the neck was opened and an abscess was found extending into the superior mediastinum. Dakin's treatment was instituted. The convalescence was uneventful and the patient was discharged as cured Aug. 28, 1934.

CASE 9.—F. E., a white youth aged 17, swallowed lye in infancy. He had been under treatment in the Jesberg clinic for many years, reporting at intervals for dilation of a stricture of the esophagus. Aug. 8, 1934, during an attempt to pass the dilator, the esophagus was perforated into the posterior medi-

astinum, just below the roots of the lungs. A roentgenogram made after the administration of barium sulfate showed the defect (fig. 8). Immediate operation was performed. With the patient under general anesthesia 2 inches of the posterior ends of the left ninth and tenth ribs were resected. The pleura was displaced outward and the mediastinum was entered. The perforation was identified by the extravasated barium preparation. Drains and Dakin tubes were inserted. The next morning the wound was filled with chyle, showing an injury to the thoracic duct. This leakage stopped after twenty-four hours. A few days later it was found that the infection had penetrated between the upper and lower lobes of the left lung. A localized empyema was drained in the axillary line. The patient made an uninterrupted recovery.

CASE 10.—M. C., aged 1 year, the only patient to recover without operation, swallowed some ornaments from a Christmas tree Dec. 25, 1934. He began to expectorate bloody mucus and to cry when swallowing. Esophagoscopy the following day showed esophageal lacerations, with a piece of glass in one. December 27 the temperature was 104 F. and x-ray examination showed the chest clear; the results of esophagoscopy examination were negative. January 8 a second roentgenogram with barium sulfate showed an abscess at the level of the second rib and another at the level of the eighth rib. The former abscess extended upward for 2 inches and communicated with the esophagus at both ends. Much pus was ejected from the nose and mouth, the temperature was 104 F. for two weeks, and then recovery took place without intervention. This case seems to show that the superior and posterior spaces have a free communication in childhood. It also shows that an occasional patient may recover without surgical intervention.

CASE 11.—A. W., a white woman aged 38, on March 30, 1935, swallowed a loose denture, which lodged in the throat. At endoscopic examination Dr. Jesberg saw the denture penetrating the esophagus and extending into the superior mediastinum

Fig. 7 (case 7).—Barium sulfate in the superior mediastinum.

at the level of the second rib. He was unable to remove or cut it. The patient, with rapidly spreading emphysema, was transferred to the Los Angeles County Hospital, where she was operated on, the following day. The mediastinum was opened through the anterior border of the right sternocleidomastoid muscle. The denture was located between the esophagus and the trachea at the level of the third dorsal vertebra. Removal was accomplished after disarticulation of the inner

Dr. Robert Hells Alderman

S. M. U. Medical College

32694 JAMES 32694

end of the clavicle. The clavicle was replaced, and Dakin tubes were inserted and irrigations started. The patient died on the following day from double pneumothorax. Death might have been prevented by a timely aspiration of the air from the pleural cavities.

CASE 12.—D. G. Mc., a white man aged 46, admitted to the Los Angeles County Hospital Aug. 7, 1935, had a history of a slight injury to the esophagus followed by cough, fever and

Fig. 8 (case 9).—A stricture of the esophagus due to lye; rupture into the posterior mediastinum.

dysphagia. On August 14 examination seemed to show a mediastinal infection. Under regional anesthesia the left side of the neck was opened and an abscess was found extending down into the mediastinum. Dakin tubes were inserted and irrigations carried out until apparent cure had been effected. Jan. 8, 1936, the symptoms recurred. A roentgenogram taken after an injection into the esophagus of iodized poppyseed oil showed the oil passing into the mediastinum at the tenth dorsal vertebra. There was considerable pulmonary involvement in both lower lobes. Before the study was completed there was a rupture of an abscess into a bronchus (fig. 9). The patient then made a good recovery. Haste in removing the tubes after the first operation resulted in a residual abscess, which gravitated into the posterior mediastinum and then ruptured into a bronchus.

CASE 13.—J. D., a white man aged 35, on Aug. 28, 1935, suffered an abscess of his left second molar. An incision and drainage were followed by swelling of the left side of the neck. September 12 a second operation showed an abscess in the left side of the neck, extending along the carotid sheath and down into the superior mediastinum. Five Dakin tubes were inserted into the abscess cavity and irrigations carried out. Rapid healing took place and an apparent cure within two weeks. Within six weeks the patient suffered a relapse and had a septic temperature, which went to 103 F., with pain and cough. The incision in the neck was reopened, and an abscess was found in the anterior mediastinum, extending down behind the sternum. The infection spread and resulted in osteomyelitis of the sternum. Another operation, December 12, with removal of the necrotic portion of the sternum and with multiple openings left resulted in a cure by March 1936.

CASE 14.—M. D., a white woman aged 32, admitted to the Eye and Ear Hospital Jan. 11, 1936, had a history of a streptococcal sore throat for five days, a temperature of 105 F. and a leukocyte count of 18,000. There was marked swelling of the left hypopharynx, as well as swelling of the left supraclavicular region. Dr. Jesberg opened the neck through the

direct laryngoscope, and later the mediastinum was opened through an approach in front of the left sternocleidomastoid muscle. Dakin tubes were inserted and irrigations carried out. Prompt recovery resulted.

CASE 15.—M. C., a white woman aged 50, admitted to the Los Angeles County Hospital Feb. 13, 1936, suffering from retropharyngeal abscess, was very toxic, had a temperature of 104.8 F., a rapid pulse, dysphagia, cough and profuse expectoration. The abscess was opened through the pharynx by Dr. Goodsel. So much pus came out that he injected the abscess with iodized poppyseed oil and later had a roentgenogram made (fig. 10), which showed the oil passing down the left retropharyngeal space into the mediastinum. It then passed over to the right side, where it entered the bronchus of the upper lobe of the right lung. March 13, 1936, under field block anesthesia, the right side of the mediastinum was opened through an incision along the anterior border of the right sternocleidomastoid muscle. The abscess was encountered at the level of the second dorsal vertebra. Dakin tubes were inserted and instillations were started, great care being used because of the bronchial fistula. Within a few days the bronchial fistula closed and the irrigations were carried out more efficiently. The temperature became normal within eight days. The patient was discharged as cured nine days after operation.

CASE 16.—M. R., a white woman aged 60, swallowed a chicken bone March 4, 1935. She suffered pain, fever and dysphagia, which gradually increased until March 10, when she was admitted to the Los Angeles County Hospital. Roentgenograms showed the bone posterior to the esophagus at the level of the sixth cervical vertebra. Her symptoms became so urgent that an emergency tracheotomy was performed by Dr. Goodsel. On the following day, under regional anesthesia, the left side of the neck was opened and an abscess was found extending down into the superior mediastinum. Dakin tubes were inserted and irrigations were carried out regularly. The patient recovered in thirty days.

CASE 17.—A. Mc. G., a white woman aged 22, swallowed a partial denture Sept. 22, 1936. It consisted of several teeth attached to a brace. She was treated in a quack hospital, where irreparable damage was done before the attempt at removal was abandoned; she was then transferred to the Los Angeles County Hospital. On her admission, September 23, the temperature was 102 F., the pulse rate 100 and the respiratory rate 24. Immediately, under regional anesthesia, the superior mediastinum

Fig. 9 (case 12).—Barium sulfate passing into the posterior mediastinum and rupturing into the bronchus.

was opened, and it was found filled with foul pus. Dakin tubes were inserted and the wound partially closed. Irrigations were carried out every two hours. Improvement took place, and the patient was apparently on the road to recovery. On the eighth postoperative day there was a sudden hemorrhage and she died. Autopsy showed that the esophagus and trachea had been terribly lacerated by the attempts to remove the denture and that sloughing of the esophagus had taken place, with fatal hemorrhage.

CASE 18.—M. O., a white woman aged 52, on June 26, 1937, while eating toast with jam, felt pain in the throat and found that the throat was bleeding. Pain in the neck and emphysema rapidly developed. She entered the Eye and Ear Hospital within a few hours. An endoscopic examination showed lacerations of the upper part of the esophagus, mostly on the right side. An anteroposterior roentgenogram showed nothing, but a lateral view showed a curved piece of glass, evidently a chip

done, but Dakin tubes were inserted and irrigations were started. The patient died of septicemia two days later. His death was attributed to refusal of early operation.

2007 Wilshire Boulevard.

ABSTRACT OF DISCUSSION

DR. SIMON JESBERG, Los Angeles: To the uninitiated, it would seem that to pass an esophagoscope is a simple matter. From all the endoscopic experience at the Eye and Ear Hospital there is no case on record in which the respiratory tract was ruptured by instrumentation. Dr. Phillips has reported twenty of our cases in which he operated. We have many more in which for some reason operation was not performed. The esophagus is a very weak viscus. Its walls are thin and it is highly intolerant of insult. From this report one would think that an endoscopist never does anything but poke holes in the esophagus. This series, however, is the concentration of well over 5,000 cases of esophagoscopy. In the case of the esophageal rupture Dr. Phillips is a little optimistic and willing to give the endoscopist a break. As a matter of fact, few foreign bodies will rupture the esophagus spontaneously. It is only when instrumentation is performed that rupture occurs. Blind instrumentation, such as the passing of a stomach tube with the idea of passing the foreign body on into the stomach, is absolutely to be condemned. I have seen several cases in which a comparatively harmless foreign body was pushed clear through the esophagus into the mediastinum. Rupture is one of the hazards of instrumentation in the removal of foreign bodies, and from a medicolegal standpoint there should be a definite understanding when passing of the esophagoscope is begun. The patient must understand that the procedure is not a simple little thing, like picking a splinter from a finger. That is often the patient's conception; because he got the foreign body so easily he expects it to come out easily. Unless there is some understanding with the patient, few endoscopists care to take the risk involved. They know, however, that they can still offer the patient a fair chance to recover should this

off the jam jar, lying in the prevertebral space (fig. 11). On the anteroposterior view, the glass was superimposed on the vertebra and was not visible. As the amount of tenderness was more on the left side, it was elected to explore that side. Under regional anesthesia the neck was opened on the left side and the piece of glass was found. The point of greatest tenderness was an accurate guide to the location of the glass. Dakin tubes were inserted and the irrigations were repeated every two hours. The patient made a rapid recovery and was able to leave the hospital within ten days.

CASE 19.—R. N., a white woman aged 69, was admitted to the Los Angeles County Hospital Aug. 31, 1937, for esophagoscopic examination. On the day following the instrumentation there were swelling of the left side of the neck, dysphagia and pain in the chest and in the interscapular region. The examination was repeated and an abscess was seen in the esophageal wall. This was opened through the endoscope and a large amount of pus was evacuated. The abscess recurred, the neck became swollen and the patient became dyspneic and cyanotic. On September 10 the neck was opened along the anterior border of the left sternocleidomastoid muscle and a large abscess was found extending into the mediastinum. Dakin tubes and drains were inserted and irrigations were carried out. The patient needed oxygen for the first twelve hours and then went on to recovery. Complete healing occurred in six weeks.

CASE 20.—S. R., a white man aged 37, on Jan. 14, 1937, was treated in the clinic for cardiospasm. Difficulty was encountered in passing the dilator. The patient went home after the instrumentation, complaining of pain, soreness and dysphagia. He was admitted to the Cedars of Lebanon Hospital when swelling, emphysema and fever were found. An x-ray examination, following the taking of a barium mixture, revealed a defect in the posterior wall of the cervical part of the esophagus. An operation was advised and refused. Two days later, with increasing sepsis, he consented to operation. Under regional anesthesia the left side of the neck was opened along the anterior border of the sternocleidomastoid muscle and an abscess was encountered. No further exploration was

Fig. 11 (case 18).—A piece of glass, indicated by arrow, perforating the esophagus and emphysema in the prevertebral space.

catastrophe occur. An impacted foreign body such as a bone in the esophagus may defy removal without rupture, or it may cause a rupture and the physician not know it. Of course it is easy to tear the esophagus without a foreign body being present, by forcing the tube when the position is not proper. How does the endoscopist know that he has ruptured the esophagus? If the rupture is of any size, an immediate emphysema will show in the neck. When such an emphysema occurs he can be almost certain that he has ruptured the esophagus.

The patient must be watched carefully. Not all require opening of the mediastinum. However, as soon as it is obvious that there is a leak through into the mediastinum, drainage should be instituted; one should not wait for actual sepsis in the mediastinum. In connection with the child who swallowed fragments of glass Christmas tree ornaments, this child did not recover spontaneously; he recovered because, in the search for small glass fragments in the esophagus, the mediastinal abscess was inadvertently ruptured into the esophagus and drainage thereby provided.

DR. CHARLES E. PHILLIPS, Los Angeles: This subject should be taken seriously, and patients should be given a real chance for recovery. Infection in the mediastinum is not a fatal condition unless it is allowed to remain untreated.

TRUE AURICULAR FIBRILLATION COMPARED WITH MUSCLE TREMORS OF POLIOMYELITIS

JAMES E. CARROLL, M.D.
HARTFORD, CONN.

Somatic muscle tremors are of an intrinsic origin and will complicate auricular fibrillation. Lewis stated that "when a somatic muscle tremor is coarse, the curves present difficulties with doubt as to whether a given series of oscillations are of somatic or cardiac origin." Two cases illustrating comparative analyses are presented to show the apparent similar electrocardiographic tracings in two divergent clinical manifestations such as (1) auricular fibrillation and (2) poliomyelitis with subjective somatic tremors simulating auricular fibrillation. Brief introductory remarks will be made regarding auricular fibrillation and complicating artefacts intrinsically.

The absolute factor or factors are many in auricular fibrillation without any specificity. That the condition arises paroxysmally or permanently is conclusively shown by the predominance of literature on the subject and by the experiences of all physicians in every medical field. Lewis,¹ Luten and Jeffreys,² Brill,³ Friedlander and Levine,⁴ Smith,⁵ Fowler and Baldrige,⁶ Yater,⁷ Frothingham,⁸ Evans,⁹ Parkinson and Campbell,¹⁰ White,¹¹ Stroud¹² and Pardee,¹³ along with innumerable other prominent workers, have found auricular fibrillation to exist with such conditions as rheumatic heart disease, arteriosclerosis and hyperten-

sive vascular disease, acute coronary thrombosis, thyrotoxicosis, chemical poisoning, alcoholism, infectious fevers, postoperatively and in congestive heart failure, the last named adding to the gravity of auricular fibrillation and, conversely, a persistent auricular fibrillation ultimately resulting in heart failure. Basically, auricular fibrillation is a mode of action of the auricles in which the fibers contract incoordinately. This obviously causes the ventricles to respond irregularly, as many impulses reach the ventricle at variable intervals. This auricular disturbance is accountable for approximately 50 per cent of the cardiac arrhythmias.

1. In auricular fibrillation there is an absence of a P wave preceding each ventricular wave. 2. In the interval between ventricular responses there are continual fine wavelets varying in height, width and rate. 3. The wavelets are more prominent in mitral stenosis. 4. A fast ventricular rate may obscure such oscillations. 5. The T wave is deformed if prominent. 6. Standard, precordial or esophageal leads can be used for the detection of such an arrhythmia.

One is familiar with the fact that in poliomyelitis following an acute attack, the patient is left with a

Fig. 1 (case 1).—Poliomyelitis. The heart is normal. R. A., right auricle; A. A., ascending aorta; K., aortic knob; L. A., left auricular appendix; L. V., left ventricle; S. V. C., superior vena cava; P., pulmonic curve.

weakened musculature. Wagoner¹⁴ shows that the following muscles are involved in the lower extremities: hamstrings, tibialis anticus, peroneals, gastrocnemius and soleus. In the upper extremities the deltoid and brachial muscles are involved. If the vagus is involved there is hoarseness of the voice or loss of voice.

Carter¹⁵ has mentioned artefacts of an intrinsic nature occurring from muscular tension, tremor or tic, voluntary muscular contractions and high resistance of the skin.

In case 1 these factors relative to the associate causes of auricular fibrillation are absent. On the contrary, the evidence presented tends to establish the fact that, apart from the fibrillation, the heart is normal.

CASE 1.—History.—A. H., a woman, aged 22, a school teacher, complained of a throbbing sensation over the right side of the neck Oct. 23, 1936, of one week's duration. At 2½ years of age she had infantile paralysis which left both legs paralyzed;

now the right leg is flaccid and limp, necessitating a brace for the entire extremity. The left leg is now much larger and healthier in appearance than the right but not normal. At 7 years she had diphtheria, and during the last five years she had one attack of tonsillitis. The teeth are good. The tonsils are buried and unhealthy. There were no abnormalities over the region of which she complained. Her voice was somewhat hoarse. Auscultation revealed a heart rate of 74 beats to the minute, of fair quality, and there were no murmurs. The lungs

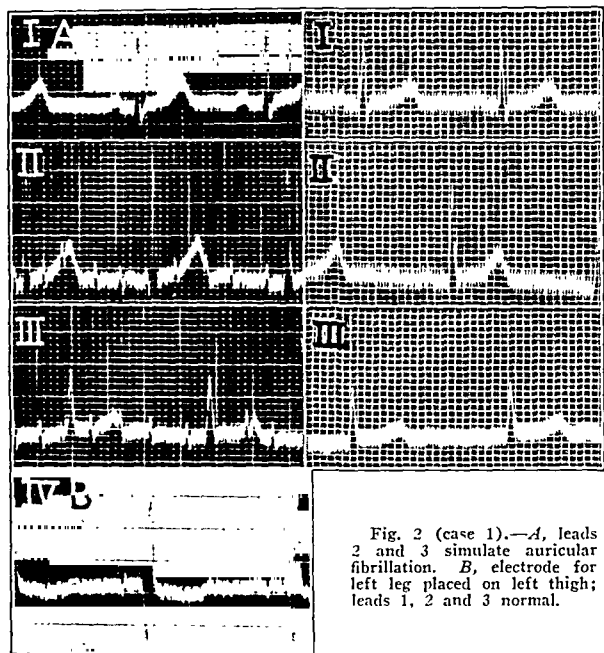

Fig. 2 (case 1).—A, leads 2 and 3 simulate auricular fibrillation. B, electrode for left leg placed on left thigh; leads 1, 2 and 3 normal.

showed slight congestion. The knee jerks were absent. The lower extremities were as already described, the right being decidedly flaccid and the left, on close examination, objectively slightly abnormal.

Fluoroscopy.—The lung fields lighted up well. There were a few scattered shadows in the regions of both hili. The diaphragm excursions were normal. The heart was medially placed and appeared normal in size. The movement of the heart from the aortic knob downward through the ventricles was a regular seesaw motion. The pulmonic curve appeared normal. The curve of the left border was convex. The lower curve of the right border was contracting very mildly inward concomitantly with the pulsations of the left auricular border. A normal condition was disclosed.

Röntgen Examination.—The transverse diameter of the medial right (3.5 cm.) plus that of the medial left (7.5 cm.) equals 11 cm. The longitudinal diameter equals 12 cm. These measurements for the patient's weight and height are normal as adopted by Polevski¹⁶ (fig. 1).

A standard electrocardiogram was taken. The patient's brace was removed and left off during all subsequent tracings. The electrocardiograms were taken by the standard orthodox accepted method of Einthoven. With the electrodes in place on the right arm, left arm and left leg, and all attached to the galvanometer, a millivolt caused an excursion of 1 cm. of the string. This standardization applied throughout to all leads. The result showed the first lead to be normal except for an irregular spacing of the ventricular complexes (sinus arrhythmia), with the ventricular rate varying from 50 to 70 beats a minute. The second and third leads resembled those of auricular fibrillation. The "fibrillation" waves were visible in diastole, and also in the T waves with an absence of P waves (fig. 2). These tracings were checked and obtained each time. Then I sandwiched the patient between two normal persons. The

control subjects gave normal tracings in all leads, but the patient with the paralysis still presented the twitchings as before.

The following questions were propounded by me:

1. Is this a true auricular fibrillation?
2. Is this a vagotonia? Bramwell¹⁷ reported an auricular fibrillation from injury to the vagus nerve.
3. Is this change from sinus arrhythmia in lead 1 to questionable auricular fibrillation in leads 2 and 3 neurogenic?
4. Is infantile paralysis formerly with resultant pathologic changes to the anterior horn cells and neuromusculature of the lower extremities accountable for this phenomenon in leads 2 and 3?

Dr. Horatio B. Williams of Columbia University offered me the following suggestions and proof:

1. The notchings are not auricular fibrillation or auricular flutter.
2. They are not artefacts in the electrocardiograph.
3. In his opinion they were muscle tremors from the left leg.
4. The application of one electrode on the left ankle and another electrode on the left thigh should show the same sort of notchings from the muscle tremor.
5. One electrode should be applied on the left ankle and another electrode on the right ankle.
6. These procedures then would give a record of the muscle twitchings independently of an electrocardiogram.

It is accepted by cardiologists in taking a standard three lead electrocardiogram patterned after the Einthoven method, if such a procedure is impossible because of the loss of an extremity (amputation), that the electrode for that extremity be placed above the stump terminus. With this thought in mind, although an amputation was not done here, I placed the left leg electrode on the lateral part of the left thigh. The three standard leads were then taken and were normal. The notchings were absent (fig. 2B). Therefore, the notchings are somatic in the left leg, as

Fig. 3 (case 2).—A, electrodes placed on left thigh and left ankle; somatic muscle tremor isolated independent of an electrocardiogram. B, electrodes placed on right ankle and left ankle; somatic muscle tremor is isolated but was the complicating factor in figure 2A. C, electrode for right arm placed on left leg, and that for left leg placed on right arm; a reversed electrocardiogram with notchings due to left leg.

they are present only when the electrode on the left leg is placed in its normal position on the left leg and absent when placed on the thigh.

In following Williams' suggestion for proof 4, the right arm electrode was applied to the left ankle and the left leg electrode was applied to the left thigh with the selector switch turned to lead 2. This resulted and showed notchings of the left leg independent of an electrocardiogram (fig. 3A). In figure 2 these notchings were the simulating and complicating anomalies, as the left leg is used in standard leads 2, and 3.

16. Polevski, Jacob: *The Heart Visible*, Philadelphia, F. A. Davis Company, 1934, p. 60.

17. Bramwell, Crighton: Can a Head Injury Cause Auricular Fibrillation? *Lancet* 1: 8-9 (Jan. 6) 1931.

Then the left arm electrode was applied to the right ankle, and the left leg electrode to the left ankle with the selector switch turned to lead 3 (suggestion 5). This tracing shows the same notchings independent of an electrocardiogram (fig. 3 *B*). In figures 3 *A* and *B*, 1 millivolt caused only 8 mm. of deflection.

Finally the electrode for the right arm was placed on the left leg and that for the left leg electrode was placed on the left arm with the selector switch turned to lead 2. This gave a negative QRS, also with notchings in the electrocardiogram. The process was reversed with the left leg in play (fig. 3 *C*).

CASE 2.—J. C., aged 74, has a typical rheumatic heart with mitral valvular involvement along with arteriosclerotic factors to show auricular fibrillation as compared with somatic intrinsic muscular notchings. The electrocardiogram (fig. 4 *A*) shows auricular fibrillation before digitalis therapy, a right

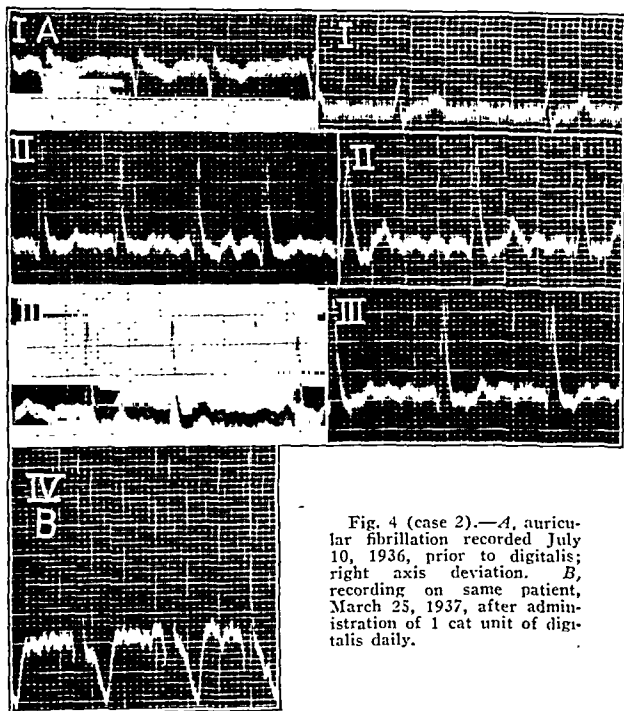

Fig. 4 (case 2).—*A*, auricular fibrillation recorded July 10, 1936, prior to digitalis; right axis deviation. *B*, recording on same patient, March 23, 1937, after administration of 1 cat unit of digitalis daily.

axis deviation, a fast, irregular ventricular rate, no PR interval, normal QRS, 0.08 second, and slurring and thickening of R in leads 2 and 3. There is a negative T in lead 1 and a diphasic T in lead 2. This tracing then shows an auricular fibrillation with evidence pointing to myocardial degeneration complicated by coronary changes. Eight months later (fig. 4 *B*) a tracing was taken from the same patient after receiving 1 cat unit of digitalis daily during that time. The wavelets are prominent and the ventricular rate, though irregular, is down to 82 beats a minute, compared to a previous variation of from 110 to 130 beats eight months before.

COMMENT

Katz and Korey¹⁸ found it necessary to adopt unorthodox leads in attempting to evaluate electrical deflections because of the varying conductivity of structure. The somatic tremor in the patient who had had poliomyelitis was subjective and intrinsic. It was picked up and isolated by the electrocardiograph.

Obviously the somatic muscle tremor as seen in figure 2 *A* in leads 2 and 3 presents difficulties and doubt as to such oscillations being of somatic or cardiac

origin. Clinically, however, that doubt is solved, and the methods as outlined by Williams will clear up the underlying disturbing factors electrocardiographically.

SUMMARY

1. These two cases are compared to illustrate the similarity of somatic muscle tremor as obtained on a patient with the aftermath ravages of poliomyelitis and on one with a true rheumatic heart disease with arteriosclerotic involvement showing true auricular fibrillation.

2. The evidence present in the case of poliomyelitis tends to establish the fact that, apart from the fibrillation episode, the heart is normal.

3. The associated clinical pathologic conditions found in true auricular fibrillation are not found in this particular poliomyelitis patient.

4. In figure 2 *A*, leads 2 and 3, there is an absence of a P wave preceding each ventricular wave. These notchings complicate correct interpretation. They simulate auricular fibrillation.

5. Proof is established that the twitchings or notchings in figure 2 *A* are not true auricular fibrillation or auricular flutter.

6. Proof is established in figure 2 *B* and figure 3 that the notchings were of somatic origin and located in the left leg.

7. The electrocardiograph did not have anything to do with the production of these intrinsic artefacts (fig. 2 *A*).

8. The electrocardiograph by unorthodox placing of electrodes on the body offers a method of detecting subjective tremors aside from an electrocardiogram.

Clinical Notes, Suggestions and New Instruments

FEMORAL OVARIAN HERNIA

FRED H. BOWEN, M.D., BALTIMORE

In 1924 Watson¹ was able to collect the reports of only twenty-two instances of femoral hernia in which the ovary was the sole occupant of the sac. A careful survey of the literature reveals that only one case has been reported since that time. In view of the rarity of this condition the following history is recorded. (The case is from the practice of Dr. N. W. Bonelli.)

REPORT OF CASE

Mrs. E. W., a white woman aged 38, admitted to the West Baltimore General Hospital, Aug. 24, 1937, complained of severe pain in the right femoral region of eleven days' duration.

The family history revealed no familial disease or hernia. There was a questionable history of rheumatic fever at the age of 5 years. The patient has been married for nineteen years. She has two children, one 18 and the other 9 years of age.

There was a long history of constipation. There were no cardiorespiratory or genito-urinary symptoms. Menstruation began at the age of 13 years but soon stopped and began again at the age of 15. It occurs in cycles of twenty-eight days and lasts from three to four days. There has been pain in the lower middle part of the abdomen one day prior to the periods "for many years."

About twelve years before admission she experienced an occasional dull pain in the right femoral region. Ten years before admission, when five months pregnant with her second child, she moved the piano. While doing this a small painless lump appeared in the right femoral region. This soon disappeared. Seven years later it was noted that the lump had

18. Katz, L. N., and Korey, H.: The Manner in Which the Electric Currents Generated by the Heart Are Conducted Away, *Am. J. Physiol.* 111: 83-90 (Feb.) 1935.

1. Watson, L. F.: *Hernia*, St. Louis, C. V. Mosby Company, 1924.

reappeared. It was about the size of an almond at that time. Aug. 12, 1937, she jumped up to remove some clothes from the line and experienced severe pain in the right groin. At the same time a lump appeared in the right femoral region and this had been present ever since. There was no nausea, emesis or diarrhea. Pain was severe and had persisted. It did not radiate. Aug. 16 Dr. Bonelli was consulted and he placed the patient in bed with an ice cap to the femoral region. The pain abated somewhat but did not completely subside. No history was obtained of any endocrine disturbances.

Physical Examination.—The patient was somewhat apprehensive, well developed and nourished and looked her age. No abnormalities were found except a mass about the size of a small hen's egg just below the right inguinal ligament in the region of the femoral canal. This mass was firm and gave one the impression of being nodular. No impulse was elicited on coughing. Pelvic examination was negative.

The urine and blood studies were negative. The Wassermann reaction of the blood was negative.

Operation.—The preoperative diagnosis was femoral hernia. The possibility of inguinal lymphadenopathy was not overlooked. Operation was done August 25, under avertin-nitrous oxide anesthesia. After the usual surgical preparation of the skin an incision was made below and parallel to the inguinal ligament. The femoral canal was exposed and found to contain the ovary. There was no well developed sac found. The point of exit was between the femoral vein and Gimbernat's ligament. The ovarian pedicle was clamped and doubly ligated with No. 2 chromic gut. The edge of the inguinal ligament was sutured to the pectineal fascia with plain No. 2 catgut. The skin was closed with black silk. The patient's postoperative course was uneventful and she left the hospital September 6 in good condition. Since operation the patient has menstruated once with no pain.

Pathologic Report (by Dr. Ralph Mostwill).—The gross tissue measured 2 inches (5 cm.) in length by about 1¼ inches (3 cm.) in diameter. The surface was smooth and on cut section showed a small amount of solid tissue on one edge giving rise to a smooth cystic area.

The first section showed young fibroblastic tissue and inflammatory tissue, blood pigment and some groups of lymphoid cells. No ovarian tissue was seen in the first section. The second section was similar in every respect to the first. There was also some myxomatous tissue present. The third section showed ovarian tissue. There was a definite ovarian stroma present. An old corpus luteum was present which contained a blood clot. There was a definite band of granulosa cells. The stroma itself was rather sparse and not quite as heavy as that seen in the normal ovary. There were several large blood vessels, several lymph spaces and a second ruptured graafian follicle.

The diagnosis was ovary showing inflammatory changes.

COMMENT

The first case of herniation of the ovary was reported by Soranus of Ephesus in 97 A. D. He did not state whether this was a femoral or an inguinal hernia. A femoral hernia was believed to be a variety of inguinal hernia until 1572, when Guy de Chaliac pointed out the distinguishing features.

The descent of the ovaries is comparable to the descent of the testicles, but it is not so extensive. At first the müllerian and mesonephric ducts lie in a ridge on the surface of the mesonephros. The ovaries gradually move caudally from their original position. They reach the false pelvis about the third month of intra-uterine life and thence they migrate into the true pelvis at birth. Their descent into the pelvis is probably due to the surrounding parts growing proportionately more than the ovarian ligaments. Ectopic positions of the ovaries are not infrequent owing to complete or partial absence of the usual descent into the pelvis. On the other hand the ovaries may occasionally descend into the inguinal canal and may even be found in the labia majora. No mention of an ovary being congenitally present in the femoral canal was found in any of three standard textbooks examined. Congenital femoral hernia is a rare entity. In view of these and other facts it seems as if in the case reported here the hernia was acquired. The anatomy of femoral hernia may be found in any textbook.

The question of the etiology of hernia of the internal genital organs involves many factors. Heredity is frequently mentioned in the etiology of hernia. In support of this are cited many cases of three or four hernias occurring in the same family. Also to be considered are conditions associated with increased mobility of the uterine appendages, such as lengthening of the broad ligaments consecutive to repeated pregnancies. Because of the loose attachment of the ovaries to the broad ligaments, they are easily affected by the pathologic and physiologic displacements and movements that affect the pelvic organs. In this connection may also be mentioned pathologic relaxation of the uterine ligaments due to puerperal subinvolution. Abnormal length of the ovarian ligaments is also of importance. Lockwood and others² consider abnormal length of the mesovarium as the principal cause of ovarian hernia. In addition there are the conditions tending to increase of intra-abdominal pressure. A sudden increase in intra-abdominal pressure, a fall or coughing, may be the precipitating cause of the development of a hernia. Occupations necessitating repeated muscular effort such as lifting probably predispose to the formation of hernia. Physiologic or pathologic states that distend the abdominal cavity and enlarge the orifices usually present in the muscular and aponeurotic layers are important. Examples of these states are enteroptosis, obesity, abdominal tumors, ascites and pregnancy. All conditions that weaken the abdomi-

Artist's conception of the reported case.

nal wall are of etiologic significance. Among these may be mentioned acute or chronic diseases debilitating the organism, especially such as cause great emaciation, obesity and traumatism.

Femoral hernias most often contain omentum. If small intestine is present it is strangulated. Sometimes the sac contains the colon, cecum, appendix and bladder. Very rarely it contains the ovary, fallopian tube, uterus, testis, kidney, gallbladder and liver. Ahrens and Speigel³ reported cases of incarceration of the stomach in the sac of a femoral hernia. The incidence of the internal genital organs in the order of frequency with which they are found in hernial sacs is ovary and tube, ovary, tube alone, nonpregnant uterus, pregnant uterus.

In hernias of short duration the herniated ovary is usually normal. Because of its position it is subject to trauma and circulatory disturbance. The position of the ovary in a hernial sac is unfavorable to its functional and anatomic integrity. Atrophy may occur, but it is usually not severe enough to check ovulation or menstruation. Cases of tuberculosis of the herniated ovary have been reported. In Mueller's³ case of femoral ovarian hernia the ovary was cystic and two fibromyomas of the ovarian pedicle were present. The ovary may be enlarged, cystic, infiltrated with blood, the seat of a large hematoma or adherent to the sac, or it may present areas of suppuration or show gangrenous changes. One spindle cell sarcoma of the ovary has been found in a hernial sac. A

² Cited by Heineck.³

³ Mueller, M. P.: Hernie crurale de l'ovaire par effort, Bull. et mém. Soc. d. chir. de Paris 24: 162-166 (March 4) 1932.

cystic ovary "the size of a man's head" was reported. In short, the conditions which affect the ovary in its normal position may be found in the herniated ovary. In addition, other disorders due to torsion, strangulation and trauma to the exposed ovary are seen.

Symptoms of herniation of the ovary are rare in children. The special sensitiveness of the ovary is said not to appear before the age of puberty. Enlargement and increased tenderness of the hernial swelling during the menstrual period are occasionally noted. Pain in the herniated ovary is usually most pronounced with the menstrual periods. Dysmenorrhea has been reported in femoral and inguinal hernia of the normal tube and the normal ovary. The ectopic ovary is hypersensitive, probably because of constant irritation. Irritation of the herniated organ may give referred pain or sensation to other organs of the reproductive system. Occasionally very severe pain is present, as in the case here reported.

According to Heineck,⁴ any irreducible mass in the femoral or inguinal region in a woman should lead one to suspect herniation of the internal genitalia. Diagnosis is difficult. On pelvic examination the fundus of the uterus is apt to be deviated to the side of the hernia,⁴ and the cervix is deviated toward the opposite side.³ If the uterus is manually moved toward the sound side it exerts traction on the herniated ovary.

Prompt surgical reduction and repair of the femoral hernia is the proper treatment. Too violent attempts at reduction of the herniated internal genitalia may result in harm to their anatomic and physiologic integrity. Trusses are notoriously inadequate in the treatment of crural herniation. In view of this and of the trauma caused by the truss it has small place in the treatment of this condition. Early correction in children is advisable in order to prevent developmental defects. Occasionally it is necessary to amputate the herniated ovary because it cannot be reduced, as in the present case.

Rayner and Dukeland avenues.

TICK PARALYSIS IN SOUTH CAROLINA

J. HEYWARD GIBBES, M.D., COLUMBIA, S. C.

Tick paralysis has been recognized in some of the Midwestern states for a number of years. It is an ascending type of paralysis, following the course of Landry's disease, at times resulting in death from bulbar involvement, associated with the bite of ticks and promptly disappearing when the feeding tick is found and removed.

Brief reference is made to the subject by Osler and McCrae¹ in which they state that the genus *Ixodes* and the genus *Dermacentor* are both capable of producing this type of paralysis.

They refer to reports of cases from British Columbia, Wyoming, Montana and possibly Australia.

Tyzer² states that ticks of the genus *Ixodidae* are responsible for a paralysis occurring in sheep and in children, and that bites along the vertebral column and head are

Fig. 1.—Wood tick attached to scalp in right occipital region.

most prone to result in the paralysis. He speaks of the condition as having occurred in Oregon, British Columbia, Australia and South Africa.

Barnett,³ in reporting a case of tick paralysis from the state of Washington, identifies the tick responsible for this condition

as the Rocky Mountain wood tick, *Dermacentor andersoni* Stiles, and calls attention to the fact that this tick has been found in thirteen states roughly adjacent to the Rocky Mountains while tick paralysis in man has been reported only from the five states of Montana, Oregon, Wyoming, Idaho and Washington.

Tick-borne diseases are now recognized as occurring in the eastern part of the United States. Badger, Dyer and Rum-

reich⁴ have reported on infections of the Rocky Mountain spotted fever type in general, and Montgomery⁵ and Mayer⁶ have reported cases of this type that have occurred in the state of South Carolina. Consequently the recognition of a case of tick paralysis in South Carolina becomes a

Fig. 2.—At left, dorsal view of tick; at right, ventral view of tick after removal from patient's scalp.

matter of more than passing interest in that it is probably the precursor of other cases in which prompt recognition is the one effective means of handling.

Paralysis resulting from the bite of a tick is presumably due to a noninfectious toxin which is liberated into the blood of the host while the tick is feeding. Experimental tick paralysis has been produced in animals by permitting female wood ticks to feed on them for a period of from one to two weeks, but it has not been found possible to transmit the disease by the blood of the affected animals or from the intestinal contents of the feeding ticks. The toxin responsible for the paralysis is supposed to come from the salivary glands of the ticks. Barnett refers to the work of Regendanz and Reichnow, who found that an extract of eggs from the common dog tick, injected into dogs, produced muscular weakness in the large animals and paralysis and death in the smaller ones.

Except for the fact that tick paralysis usually develops after a female tick has fully fed on the host, at which time, in nature, she is impregnated and ready for egg laying, there is nothing to suggest that the tick egg is related to tick paralysis in man. It is assumed that a feeding period of from five to six days is required for the tick to inject sufficient toxin to produce the changes in the central nervous system that lead to paralytic phenomena.

The symptoms usually begin in the lower extremities.

Paresthesias, numbness and tingling frequently appear first but are quickly followed by muscular weaknesses and incoordination. The weakness may progress to complete flaccid paralysis. The upper extremities are then involved in similar fashion, and this is followed by indications of bulbar involvement, difficulties in speech, respiration and deglutition. If the tick is found and removed, there is a remarkably rapid reversal of the signs and symptoms, and a threatening condition in large part disappears within a period of from twenty-four to forty-eight hours. If the tick is not discovered, the bulbar paralysis may lead to death, especially in the case of children, while adults tend to have a slow, spontaneous recovery.

REPORT OF CASE

The following case presents a classic example of tick paralysis:

History.—Mrs. H. E. T., a resident of Columbia, S. C., while on a visit to Greenville, went on June 19 to inspect some prize pigs. Four days later she experienced the sensation of tingling and numbness in the lower extremities. In the latter part of the same day the legs felt weak and she "did not know just where they were going." The next morning her legs would not support her body and she noticed numbness and tingling in the upper extremities. She was brought to Columbia in an ambulance, and, on arrival, stated that she was aware of a weakness in the arms and hands. She had had no difficulty in talking or swallowing. She was greatly alarmed about herself.

Physical Examination.—The patient was of fair nutrition and good color. She was in a semihysterical condition. The skin showed no abnormal eruptions or pigments. The eyes were not prominent, the pupils were equal and reacted normally, the extrinsic eye muscles functioned normally, and there was no nystagmus and no icterus. The nose, ears and throat were negative. The teeth were false. The thyroid was not enlarged. There were no enlarged lymph glands. The heart was not enlarged, the sounds were clear at the apex and base and the heart action was slow and regular. The lungs were clear. The abdomen was of normal appearance. There was no tenderness. There were no masses and no palpable organs. The extremities showed no edema and there was no fine tremor of the fingers. The joints were negative. The pulse was 92 and regular. The temperature was 100 F. (5 p. m.). The blood pressure was 140 systolic, 80 diastolic. The eyegrounds showed no abnormalities.

Neurologic Examination.—The muscles showed some loss of strength in the legs with definite incoordination in the movements. The knee to heel test showed pronounced ataxia, and the movement was carried out with extreme difficulty. There was no demonstrable weakness in the upper extremities. Sensation gave normal response to all modalities throughout. The Babinski responses were normal. The ankle jerks and knee kicks were absent. The abdominal skin reflexes were not present. The deep tendon reflexes at the wrists and elbows were present. The jaw jerk was normal.

Course.—June 25 the weakness in the lower extremities was more pronounced. There was demonstrable weakness in the muscles of the arms and hands and there was definite ataxia in the movements of the upper extremities.

June 26 the weakness and ataxia in the upper extremities was so pronounced that the patient could not feed herself.

June 27 the patient stated that she thought her legs felt somewhat better. But her upper extremities had shown no improvement and her speech had become thick. She had had no difficulty in swallowing. She called attention to a "tumor on the scalp" which had been found by a nurse in combing her hair. Inspection showed a fully distended wood tick, measuring 1.5 by 1 cm., attached to the right occiput. The tick was removed.

June 28 the patient stated that she "felt better all over."

June 29 the patient seemed entirely well. The knee kicks had returned and the abdominal skin reflexes were present. The impediment in speech had disappeared.

July 1 the patient was dismissed from the hospital.

On admission to the hospital the patient's temperature was 100 F. This was the only rise above normal throughout the course of illness. The laboratory studies on the blood, urine and stool were unimportant.

July 15 the patient was at my office and seemed none the worse for her experience.

CONCLUSIONS

A case of tick paralysis occurred in South Carolina. Attention is called to it because of the importance of recognizing this condition as a possibility in the eastern part of the United States and of the necessity for finding the tick and removing it as a means of curing the patient.

Special Article

HUMAN REQUIREMENTS FOR
VITAMIN B₁

GEORGE R. COWGILL, Ph.D.

Associate Professor of Physiological Chemistry, Yale University
NEW HAVEN, CONN.

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

Other papers in this series discuss the chemistry of vitamin B₁, the pathology of vitamin B₁ deficiency and the physiologic function of this dietary essential. What can be said concerning the amount of this vitamin needed by man?

As beriberi is due to lack of vitamin B₁, it is natural that the earliest estimates of the human requirement of this factor should have been in terms of the therapeutic value of certain foods. For example, Hulshoff-Pol¹ studied the efficacy of katjang idjo, a native bean (*Phaseolus radiatus*), in the cure of beriberi. The practical result of this type of investigation was to focus attention on the importance of foods containing vitamin B₁ and therefore their inclusion in the dietary. All work along this line prior to about 1911, when Funk² introduced the word "vitamine," necessarily suffered the disadvantage that controversy still prevailed respecting the exact cause of beriberi and therefore the validity of any dietary measures in its treatment. In 1907 Braddon³ published his impressive monograph "The Cause and Prevention of Beriberi," in which he championed the idea that subsistence on a white rice diet is responsible for beriberi, but explained the disease as due to a toxin present in the rice. Although this explanation was later shown to be erroneous, Braddon's book has rendered a great service to students of beriberi because it contains a vast amount of information relating to beriberi epidemics. This material was reexamined in the light of the deficiency disease hypothesis by Vedder,⁴ whose book appeared almost immediately after the word "vitamine" had been suggested by Funk. When it had become clear that beriberi is fundamentally a vitamin deficiency and that it is possible to study the protective factor in experimental animals, a new kind of evidence⁵ bearing on the question of the human need for this vitamin appeared in the scientific literature, evidence based on comparisons of the requirements of different species of animals and their suggestions for the human species. For the ideal type of information needed to answer the question of the human requirement for this vitamin it was of course necessary to await isolation of the factor in pure form and tests of it on the human species, something accomplished only

recently.⁶ In the light of this development of the subject it must be obvious that it has not as yet been possible to make as many tests with the pure vitamin as might be desired, but that these may reasonably be expected in the near future.

From Osborne and Mendel's⁷ quantitative experiments in 1922, designed to determine the rat's need for vitamin B, it became clear that the requirement for this factor increases with increase in body weight. In 1923 I was much impressed with the fact that, per unit of body weight, the rat was found to require roughly five times more vitamin B (or vitamin B₁, according to the newer terminology) than the dog. This suggested that man, a still larger species, might be found to require relatively even less than the dog. From what was known at the time regarding the adequacy of human diets and the rat's need for vitamin B₁ it was evident that man could not possibly require relatively as much as the rat. It occurred to me that quantitative experiments on as many species as possible might lead eventually to knowledge applicable to man. Such experiments were therefore made on four species, the mouse, rat, pigeon and dog. All of these tests were made with the same vitamin B₁ concentrate in order to avoid error due to the presence of unknown dietary essentials, the amounts of which might vary in different materials. Preliminary observations of cures of animals suffering from advanced B₁ deficiency gave such variable results that it was decided to make the desired quantitative tests on animals as nearly normal as possible. Therefore the prevention of the characteristic anorexia which appears in response to lack of vitamin B₁ was made the physiologic sign of interest.

When the minimum dosages of vitamin for a given species were plotted on coordinate paper against body weight, a curve resulted. Attempts to secure a straight line finally resulted in the discovery that the dosage of vitamin was in an approximately linear relationship to the body weight raised to the five-thirds power. This first approximation type of relationship was found to hold quite well within the ranges of body weight studied in the four species, a fact which naturally suggested that it would also hold for the human species. It was further observed that the values of the equating constant ($K_{v,1}$), derived from the plots of data for the various species, were in some way related inversely to the "average maximum size" of the species, the mouse requiring the most and the dog the least per unit of body weight, with the rat and the pigeon in appropriate intermediate positions.

Obviously it was necessary to determine in more detail the nature of this inverse relation to body size if the human requirement was to be found. This was finally achieved with accuracy sufficient for the purpose by comparing the various species on the basis of a new variable called the maximum normal size of the species. When this was done it was possible to place all the species on the same straight line with respect to the vitamin B₁ requirement. It was then evident that a value for the human requirement would be suggested by the "maximum normal weight" for man. Data on weight were secured from actuarial tables and a formula then constructed by which to express man's need for vitamin B₁.

The next step in the investigation consisted of actual tests of this expression to determine its validity and limitations, if any. In order to do this it was necessary (1) to estimate as accurately as possible the vitamin B₁ content of various diets known to have been associated with the presence or absence of beriberi and (2) to apply the new formula to the persons who ate those diets. This is hardly the place to review the results of the study in any detail; the interested reader is referred to the monographic report.⁸

Let it suffice to point out that examination of numerous diets known to have been associated with epidemics of beriberi revealed that their contents of vitamin B₁ were indeed too small to have met the estimated needs of the persons subsisting on them; therefore beriberi should have appeared, as it did. Likewise, numerous diets known to have been associated with absence of beriberi were found to contain amounts of the vitamin above those estimated to have been required by the persons eating them. These calculations naturally required some knowledge of the vitamin B₁ content of numerous foods, and a large body of information was obtained indirectly from consideration of assay data in the literature. It is worthy of note that a similar study of beriberi diets made by Baker and Wright,⁹ using for the calculations the results of food assays made by the same method in the same laboratory, has yielded essentially the same results. Another confirmation has come out of the work of Van Veen⁹ carried out in Java.

In this connection it is pertinent to point out that I have always considered the formula derived from this research as constituting merely a first approximation. In the final chapter of my monograph I particularly invited the cooperation of workers everywhere in the confirmation or determination of limitations of these results and the deductions drawn from them. Considering the indirect nature of the approach to the problem, the necessity for making numerous assumptions, and the possibilities resident in further researches in this field, it would be most surprising indeed if the results of this first approximation study should not require modification as a result of later discoveries, particularly those made possible by the isolation and ready availability of the pure vitamin.

Certain difficulties in my work, to which a critic might call attention, have always been appreciated. For example, in the rat the five-thirds power relationship, strictly speaking, applies only to animals ranging from about 70 to 150 Gm. in body weight, for the data obtained and discussed were yielded by animals of this size. It may be a quite unjustified extrapolation to apply the formula to larger animals. However, it is certainly significant that when Drs. W. H. Eddy and M. Kellogg repeated the study on rats they found precisely the same relationship to hold with animals up to about 150 Gm. weight; with larger animals, however, the formula did not hold. It may be that the formula stands in some relation to growth, or more particularly the changing caloric exchange characteristic of growth, and this idea receives support from the work of Hendricks.^{9a} On examination of the caloric intakes of rats of different weights, taking for example the food intake

data of Osborne and Mendel cited in my monograph (on page 82), one obtains over the range of weights covered by these vitamin B experiments a curve similar to the ordinary growth curve, but after about 150 Gm. of body weight the plot of caloric intake against weight proves to be practically a straight line with caloric intake increasing slowly with increasing body weight. In view of these considerations it is quite possible that the five-thirds power relationship set forth in the vitamin formula does not apply to these large rats but that some other relationship holds. The same point of view applied to the dog may help to explain why the five-thirds power formula gives as the quantity of vitamin B required by a large Newfoundland dog, for example, an apparently altogether too large amount.

I am also aware that my plot of species vitamin constant against maximum normal weight of the species involves a plot of logarithms against logarithms, and therefore the points actually plotted may represent appreciably variable instead of quite fixed values. Even in the face of this fact it appears obvious to me that one still obtains as the outstanding feature of the resulting plot a definitely inverse relationship of species vitamin B₁ requirement to maximum normal size of the species. Furthermore it seems especially significant that it was from this particular plot that a suggestion was obtained of the appropriate constant to use in the formula applicable to man; and tests of the formula thus derived on various human diets have given essentially the same results as those yielded by other workers who have used more recent and exact data on vitamin contents of foods, as well as experimented with the pure vitamin. It is difficult to believe that such an outcome and confirmation of the formula can be merely fortuitous.

The formula (see table) indicates that the value of the vitamin B₁:calory ratio increases with increase in body weight. In a personal communication Dr. R. R. Williams has expressed his disagreement with this point. He feels that the fundamental relationship is merely between vitamin B and carbohydrate or non-fat calories. In the light of the newer researches indicating a probable role of this vitamin in the metabolism of carbohydrate,¹⁰ such a view is well supported. However, the question as to whether the critical value of the vitamin:calory ratio increases with increase in body size can hardly be disposed of in such simple fashion in my opinion. With the perfection of chemical methods for analysis of blood and urine for vitamin B₁ and their application in studies of vitamin B₁ physiology, it should be quite possible sooner or later to obtain data bearing definitely on this question. From certain preliminary observations which Jolliffe and collaborators have shown me it is reasonable to believe that the value of this ratio may indeed prove to vary with body weight as I have already suggested. For all practical purposes and the evaluation of human dietaries the settlement of this question may be quite academic. The final answer will probably be obtained only when experiments specially designed for the purpose have been performed.

The formula by which to estimate a given person's requirement for vitamin, as stated originally, expressed the vitamin variable in terms of the milligram-equivalent, a unit based on the particular yeast concentrate used in the studies from which the formula was derived. It is of course more desirable that the international unit be used, and a table giving factors for converting

the milligram-equivalent to the international, Sherman and other units was included in the monograph describing the formula. From a theoretical point of view the ideal unit is a given amount of the pure crystalline vitamin, i. e., thiamin chloride, and it seems likely that sooner or later the international committee will adopt such a standard. In view of these considerations, therefore, I have prepared the accompanying table, by means of which any investigator may use my formula to obtain the vitamin values in terms of the present international unit and various representative quantities of thiamin chloride. It is obvious that the value of only the equating constant is affected when different units are used for expressing the vitamin variable, and therefore only the appropriate values of K_{vit} need be given in the table.

It will be noticed that the table gives values of the equating constant for different quantities of thiamin chloride. Several investigators have reported different amounts of the pure vitamin as equal to the present international unit. The smallest and the largest quantity suggested have been 2 and 5 micrograms, respectively, which would mean that from 500 to 200 international units is contained in 1 mg. of thiamin

Table for Obtaining Vitamin Values

When vitamin is expressed in terms of the units indicated below, the value of K_{vit} to use in the formula $\frac{\text{vitamin}}{\text{calories}} = K_{vit} \cdot \text{weight in kilogram}$ is that shown in the table.

Unit of Vitamin B	K _{vit}
Milligram-equivalent (Cowgill ²)	0.0284
International unit (1934)	0.00142
Micrograms of thiamin chloride when 1 international unit is taken as equal to	
2 micrograms	0.00284
3 micrograms	0.00426
4 micrograms	0.00568
5 micrograms	0.0071

chloride. These variations are doubtless to be attributed to the fact that the different investigators have not used the same biologic test. It seems reasonable to believe that, if the international committee decides to establish a new unit based on the pure vitamin chloride, the selected quantity will be between 2 and 5 micrograms. From the data given in the table it will be a simple matter to determine what value of the equating constant to use in the formula to give the vitamin values in terms of the new international unit.

It should be emphasized that estimates of the human requirement for vitamin B derived from my formula pertain to the minimum or beriberi-preventing level; the optimal intake is undoubtedly much greater. What should be taken as the optimal requirement will be discussed later.

THE NORMAL ADULT

What does the formula suggest as the minimum vitamin B₁ intake necessary for the adult human being? Obviously the weight is significant. Also, as the formula indicates, the vitamin requirement is related to the caloric intake, and, in view of what is known about the probable function of the vitamin in the body,¹⁰ a still closer approximation would be with respect to the calories from carbohydrate metabolism. Assuming an average degree of activity and therefore level of daily energy intake, it appears that a man weighing 45 Kg. (99 pounds) requires as a minimum about 135 international units of the vitamin; a person weighing 70 Kg. (154 pounds) needs approximately 280 international

10. Cowgill, George R.: The Physiology of Vitamin B₁, J. A. M. A. 110:805 (March 12) 1938.

units, and a still heavier person weighing 90 Kg. (198 pounds) requires about 550 international units. Obviously the exact figure depends very much on the number of calories involved or taken in the calculation.

These values agree quite well with those suggested by other students of the problem. Thus Jansen, working with the small stature races of the Far East, estimated that from 1 to 2 Gm. of the international standard adsorbate was required daily as a minimum, with about 4 Gm. constituting a curative dose for patients with beriberi. Since 1 international unit is defined as the activity of 10 mg. of the standard adsorbate, his dosages can be translated to from 100 to 200 international units as the daily minimum and 400 international units for the cure of beriberi. These minimums, pertaining to people with body weights ranging from about 45 to 60 Kg., obviously agree very well with those suggested by the formula.

Reference has already been made to the relationship of the vitamin requirement to the caloric intake. As it is easy to estimate the number of calories yielded by a given diet, a simple form of standard to use in expressing the vitamin need is the number of units of vitamin per hundred calories. Stated in this way the minimums cited mean approximately 10 international units per hundred calories. Rose¹¹ has examined the reports of numerous investigators and recommended a daily intake of 30 Sherman-Chase units per hundred calories as a liberal allowance, an intake which would be equal to 15 international units per hundred calories. As pointed out by Daniel and Munsell,¹² "for the average adult this would mean between 750 and 900 Sherman-Chase units, or roughly 250 to 400 international units per day, quantities admittedly well above the minimum requirement."

Vorhaus, Williams and Waterman¹³ estimated that the normal adult takes in daily about 1 mg. of pure vitamin B₁; they did not mean that this necessarily represents a definite requirement, however. If one assumes that from 3 to 5 micrograms of the pure substance equals 1 international unit, this estimate means a daily intake of from 333 to 200 international units, which is in the range of minimums previously suggested.

Evidence of another type bearing on this question may be cited in the work of Harris and Leong.¹⁴ These investigators studied the excretion of vitamin B₁ through the kidney. The healthy adults studied by them, from 13 to 37 years of age and subsisting on normal diets, were found to excrete daily from 12 to 35 international units, or from 30 to 90 micrograms of the pure vitamin hydrochloride; this excretion was estimated to be approximately from 5 to 8 per cent of the total daily intake of the vitamin. These authors concluded that a urinary output of vitamin B₁ below 12 international units daily, or approximately 1 unit per hundred cubic centimeters, should be regarded as evidence for strongly questioning the adequacy of vitamin B₁ in the diet. On the basis of these observations the minimum daily standard for a man weighing 140 pounds (63.5 Kg.) was set at 200 international units.

It is evident that this estimate of the minimum agrees well with the others which have been cited.

Further data bearing on this question may be cited. Van Veen⁹ has suggested 150 international units per day as the beriberi-preventing minimum suited for the inhabitants of the Dutch East Indies. From their studies of numerous dietaries throughout the world Baker and Wright⁸ of London arrived at from 200 to 500 international units per day as the minimum for man. It seems pertinent to point out that the oriental races represented by the Van Veen report are normally of smaller stature than Europeans and Americans. The lower suggested minimum of Van Veen might be interpreted in the light of my formula as due to the vitamin: calory ratio having a lower value for these people of smaller body weight. Against this view, of course, it can be argued that these people eat less food and the fundamental relationship is really between the vitamin and the amount of food or number of calories ingested.

A still more recent contribution is seen in the work of a German group^{14a} of investigators, who have suggested that the minimum for man is from 250 to 750 micrograms of thiamin per day. Since there is no unanimity of opinion regarding the number of micrograms of thiamin to be taken as equivalent to 1 international unit, it is difficult to say exactly how many international units these suggestions represent. Taking 1 international unit as equivalent to from 2 to 5 micrograms of thiamin, the range covered in the table, the lower figure (250 micrograms) might be from 50 to 125 international units; similarly the larger figure (750 micrograms) could be anywhere from 150 to 375 international units. What is probably more significant is the suggestion of these German authorities that from 1 to 2 milligrams of pure thiamin daily is needed for health, which agrees with the opinion of Williams and associates.

The perfection of chemical methods for analyzing the urine and other biologic fluids for vitamin B₁ should lead to further extensive studies to determine the extent to which an injected standard dose of the pure vitamin is excreted through the kidney and the relation of the amount excreted to the store in the tissues. If the tissue reservoir is not saturated, it is reasonable to suppose that a smaller fraction of the injected vitamin will be eliminated in a standard interval of time; with the tissues already storing the maximum amounts, greater portions of the injected test dose should be eliminated. Perfection of the technic for such a test would mean that a valuable clinical function test for vitamin B₁ deficiency had been obtained.

Such an "injection-saturation-excretion technic" has already yielded valuable results in studies of the body's requirement for vitamin C. It is of course possible that the same results would not be obtained with thiamin because of differences in function in the body, etc. Some preliminary observations, which Dr. N. Jolliffe and associates have shown me, suggest that this may after all prove to be the case, that vitamin B₁ differs from vitamin C in respect to tissue saturation and elimination. The entire subject merits extended study which should lead to results useful both to public health and hygiene and to clinical medicine.

MOTHER AND INFANT

What is known about the vitamin B₁ requirement of the human mother and her infant? The high inci-

dence of infantile beriberi in certain regions is evidence of the importance of this question. In this connection it is important to bear in mind two facts: 1. During the first six months of its life the human infant subsists almost entirely on milk and is therefore in the category of persons who live on a restricted dietary. 2. The amount of vitamin B₁ present in the milk has been shown to be dependent primarily on the quantity ingested by the mother. Studies on rats¹⁵ have shown that for a lactating rat to nurse her litter successfully the vitamin B₁ intake must be about five times the amount needed for mere maintenance of the maternal organism. Studies of numerous dietaries¹⁶ used in regions where beriberi is endemic have shown that they are low in vitamin B₁ content. For example, Baker and Wright¹⁶ found the B₁ content of a group of such dietaries to range from 71 to 180 international units daily. It is not surprising, therefore, that the lactating women of many sections of the Far East who subsist on these faulty diets should secrete milk containing too small an amount of the vitamin for the infant and that infantile beriberi should be of common occurrence in these regions.

In 1935 the Technical Commission of the League of Nations Health Committee published a report entitled the "Physiological Bases of Nutrition,"¹⁷ dealing particularly with the vitamin requirements of pregnancy and lactation and recommending during these two physiologic states a daily vitamin B₁ intake of from 150 to 250 international units. This suggestion is based on daily intakes of from 3,000 to 3,500 calories during lactation. In the light of the preceding discussion such a recommendation seems altogether too low. It is of course difficult to make any all-inclusive single statement as to what the human mother should consume daily (this is what the commission was attempting to do) because the factors which must be considered do not always operate to the same degree in every person. In lactation the body weight, the total caloric exchange and the volume of milk secreted all have a part as well as the intake of vitamin. It is possible that the recommendation of the commission may be regarded as reasonably satisfactory for the average woman of certain races normally smaller in stature than our own. For the American mother, however, I believe the daily vitamin B₁ intake might well be not less than 15 and preferably as high as 20 international units per hundred calories. If for any reason it is difficult to secure these higher levels of intake, obviously the vitamin may be given directly to the infant.

More exact data bearing on this question might be secured from a study of the effects in lactating women of various levels of vitamin B₁ intake on the concentration of the vitamin in the milk secreted; the intake giving the highest concentration of vitamin in the milk and above which no further increase is produced might be taken as the standard of vitamin B₁ intake during lactation in the human species. Now that the pure vitamin is available, it should be possible to perform experiments with the desired limitation of variables not possible hitherto. Studies of the maximum retention

of doses of pure vitamin administered to lactating women differing markedly in size and caloric intake should yield data useful in relation to this question.

This problem may also be considered from the standpoint of the vitamin intake of the nursing infant. The "American Public Health Year Book" for 1934-1935¹⁸ states that the daily requirement for vitamin B₁ increases from 50 to 200 international units between infancy and adolescence. Should this lower figure, 50 international units, be regarded as a suitable optimum for the month old infant? If one considers the baby's daily caloric intake of human milk having the maximum amount of vitamin B₁ ever found, how much vitamin B₁ would the infant receive from such milk? My calculations give a figure approximately 80 international units instead of the 50 stated in the Year Book's recommendation. Until extensive quantitative studies have been made and this result shown to be erroneous, I suggest that 80 international units daily be taken as the optimum for the very young baby. One might perhaps call this a minimum, by which one would mean that no baby should receive less than this amount daily.

From theoretical considerations one should expect the vitamin B₁ requirement to be greater for growth than for maintenance. In addition to the vitamin consumed during the metabolism associated with mere maintenance of the organism, the growing person needs the vitamin which is to become a normal part of the new cells produced by growth. Furthermore, since the caloric exchange and the general level of energy metabolism are relatively higher during growth, one may also expect to find a higher vitamin B requirement for growth because of this increase in the variable in the formula representing metabolism. Dann and I¹⁹ studied this question in the rat by comparing the amount of vitamin B₁ needed to secure the good growth characteristic of our colony with the amount required for maintenance at a given body weight after the rats had made good growth to that weight. The data indicated that the B₁ requirement for good growth in the female rat is from three to five times the need for mere maintenance.

THE CHILD

What is known about the child's need for vitamin B₁? The formula discussed in the first part of this paper applies more strictly to the adult organism and gives only the beriberi-preventing minimum. Theoretically, children subsisting on a diet just sufficient for their parents should not acquire beriberi until by growth they have reached the approximate size of the parents. The primary effect of such a diet on the children would probably be some limitation of growth. This would explain why beriberi, although common among breast-fed infants of the Far East, is comparatively rare in children between the weaning age and early adult life. It becomes appropriate, therefore, to examine the growth of children in relation to the supply of vitamin B₁.

It appears evident from the reports of several investigators that shortage of this vitamin has operated in part to limit the growth of children in North America. For example, Morgan and Barry,²⁰ in their study of

underweight children, obtained weight gains from 150 to 170 per cent above the expected gain when they fed two wheat germ rolls at the noon meal; these gains may be contrasted with the gains of the control group, which received white flour rolls and made only from 50 to 71 per cent of the expected gain during the same period. Summerfeldt²¹ observed gains of 4.54 and 5.27 pounds (2 and 2.4 Kg.) in ten weeks associated with the administration each week of 4.2 ounces (113 Gm.) of wheat germ and 0.28 ounce (8 Gm.) of yeast, these supplements being incorporated in a special breakfast cereal; the control groups, receiving ordinary cereals, gained only 1.25 and 1.27 pounds (567 and 576 Gm.), respectively. An extension of this study was made by Ross and Summerfeldt,²² who also used a vitamin B₁ concentrate in addition to the ordinary cereal; their results indicated that the gain with the special cereal was in large measure due to its vitamin B₁ content. The observations of Bartlett²³ and Schlutz²⁴ of anorexia in children brought to an outpatient clinic suggest that lack of vitamin B₁ is more common than is generally appreciated.

Knott²⁵ made vitamin B₁ balance studies with eight children from 4 to 7 years of age. "In the . . . study, the intakes which resulted in the highest retentions (regardless of whether retentions were calculated on the basis of food minus urine or food minus total excretion) were found to be six to seven times greater than the minimum requirement for preventing beriberi as determined by means of the formula suggested by Cowgill." Knott also pertinently remarked: "If the intakes resulting in highest retentions may be considered optimum, this wide range between minimum and optimum requirement would seem to explain both the existence of vitamin B deficiency among children and the beneficial results obtained by additions of vitamin B to the diet." This suggested optimum for young children was expressed by Knott as "about 40 Chase-Sherman units per kilogram per day." This would be equal to about 20 international units per kilogram daily. On the basis of the data on body weight and caloric intake recorded by Knott, this figure may be translated to mean from about 20 to 25 international units per hundred calories.

CLINICAL FACTORS INFLUENCING THE VITAMIN B₁ REQUIREMENT

Heightened Metabolism.—Examination of the formula given previously reveals that the vitamin B₁ requirement is related to the caloric exchange. If the caloric factor is increased, the body weight remaining unchanged, obviously the vitamin intake must be increased. This rule has been tested experimentally both in dogs²⁶ and in pigeons²⁷ and found to be cor-

rect. The metabolism factor was increased by administration of thyroid tissue, with consequent production of experimental hyperthyroidism, and in every instance, after the appearance of anorexia, with consequent loss in body weight, the administration of sufficient vitamin B₁ restored the urge to eat and the animals voluntarily ate enough additional food to permit return to the original weight and to secure maintenance at that weight. It may clarify the significance of these results if I point out that the voluntary intake of calories during the experimental hyperthyroidism following administration of vitamin B₁ was practically twice that characteristic of the animals before thyroid was given. In other words, the level of energy exchange induced by the administration of thyroid was approximately double the normal level. In man such a difference would correspond to that seen in a case of extremely overactive thyroid.²⁸ Although it must be recognized that exophthalmic goiter may not be due simply to an overactive thyroid,²⁹ it does seem clear that patients suffering from this disease should receive considerably more vitamin B₁ than normal persons. A good practical rule to follow in such cases would seem to be to administer not less than 20 international units of vitamin B₁ per hundred calories of the estimated total daily metabolism. Even this intake would mean using a factor of safety of only 2. If one were to take the measurements of the requirements of pigeons in experimental hyperthyroidism as a guide,²⁷ a much greater factor of safety would be justified in certain cases. Some of the birds required from two to five times the normal amount of vitamin when given the thyroid. The differences may be related to variation in absorption of material from the alimentary tract and other functions. With the pure vitamin now available, extensive tests of its efficacy in the treatment of exophthalmic goiter should be made; the results of such clinical trials would provide the best basis for the formulation of rules regarding the appropriate dosage of the vitamin.

The effect of an increase in the caloric factor on the vitamin B₁ requirement has also been tested in dogs given forced exercise.³⁰ In every case, increase in the number of calories representing total metabolism was associated with an increase in the vitamin need.

These confirmations of the relationship between calories and the vitamin B₁ requirement suggest to the clinician the wisdom of increasing sufficiently the vitamin B₁ supply in all cases in which there is a significant increase in the energy metabolism. For example, in the treatment of prolonged fevers by the feeding of so-called high caloric diets, ample supplies of vitamin B₁ should be given along with the "extra" calories. How much vitamin should be given? It is difficult to make any dogmatic general statements in answer to this question. It can be suggested, however, that some estimate be made of the total daily caloric exchange and not less than from 15 to 20 international units of the vitamin per hundred calories be provided. If there is a reason to believe that the patient has been for some time on a low vitamin B₁ regimen, the daily administration of from 5 to 10 mg.³¹ of the pure vitamin for about a

31. This suggestion is based on the report of clinical trials of the pure vitamin made by Goodhart and Jolliffe.³²

week to build up the tissue reservoir would be wise; afterward the daily intake might well be not less than 15 international units per hundred calories.

Loss Through Excretory Channels.—Vitamin B₁ is a water-soluble substance and presumably, therefore, might be eliminated through the kidneys. Many workers have examined the urine for vitamin B₁ content with positive results. There appears to be little question that the amount of vitamin B₁ present in the urine is affected by the intake and the degree of "saturation" of the tissues.³² It becomes of interest clinically to know whether vigorous diuresis can operate to affect the organism's need for vitamin B₁ by promoting loss of this dietary factor through the kidneys. That this is indeed possible was shown by the experiment which Rosenberg, Rogoff and I³³ performed on dogs. We observed that mere administration daily of large volumes of water sufficient to produce vigorous diuresis resulted in the appearance of anorexia due to vitamin B₁ deficiency in about one-half the time normally required; control experiments showed that such administration of water together with ample vitamin B₁ did not produce the anorexia.

Many clinical conditions are characterized by pronounced diuresis. It seems clear from these experiments on animals that whenever the clinician encounters pronounced diuresis he should take care to see that the patient receives a sufficiently large extra amount of vitamin B₁ to replace that which may be lost through the kidneys. A factor of safety of at least 2 seems to be warranted. This would mean a daily intake of not less than 20 international units per hundred calories for the average patient; still greater amounts would of course provide a greater insurance against shortage of the vitamin due simply to loss through the kidneys.

In the treatment of many clinical conditions it has become standard practice to administer large volumes of fluid. The data at hand from animal experiments suggest the wisdom of administering liberal amounts of vitamin B₁ along with the fluid. The minimum previously suggested based on a factor of safety of 2 might well apply if the patient is an adult; if he is a child the results of Knott²⁵ should be considered and much larger doses given.

Diarrhea is a common feature of many clinical conditions. It has long been known that vitamin B₁ is present in the stools of animals and that the amount present may vary with the composition of the diet.³⁴ It is theoretically possible that some of the vitamin present in the intestinal excreta came originally from within the organism, having been excreted through the intestinal wall. Two other possibilities are (1) that this vitamin represents the amount in the diet which failed to be absorbed and (2) that it has been produced by micro-organisms, having been either secreted by them into the surrounding medium or present in the stool as part of their bodies. Study of this problem is obviously of some clinical importance. From the experiments which Dann and I³⁵ performed on dogs it is clear that the effect of diarrhea is to decrease the absorption of an appreciable fraction of the ingested vitamin. In some instances the daily intake by mouth

had to be increased as much as 70 per cent above the previous "normal" dose. No evidence was obtained suggesting the loss of previously absorbed vitamin by excretion through the intestinal wall. The diarrhea produced experimentally in our dogs would not be classified as severe; it certainly was not comparable to the pronounced diarrhea characteristic of numerous clinical conditions. If the condition we studied could produce a 50 to 70 per cent loss of ingested vitamin, it is clear that the more severe diarrheas must mean even greater losses. Two methods of treatment with vitamin B₁ suggest themselves; namely, administration by mouth of doses of the order of 20 international units per hundred calories or more, with the expectation of considerable loss due to failure of absorption, and parenteral administration of the pure vitamin in doses not less than about 15 units per hundred calories.

Clinical Trials with Thiamin Chloride.—Some tests with pure vitamin B₁ have already been reported. It is pertinent to my present theme to discuss these briefly.

Reference has already been made to the paper by Vorhaus, Williams and Waterman.¹³ These investigators suggested that adult human beings should receive daily about 1 mg. of the pure vitamin. Goodhart and Jolliffe³⁶ made a study of the efficacy of various doses of thiamin chloride in the treatment of neuritis in alcohol addicts. They observed that the minimum effective dose was of the order of 4 mg. daily; from 10 to 20 mg. gave much more valuable results, and in some cases as much as 50 mg. had to be given in order to secure improvement. Weiss³⁷ reported tests indicating the value of the 20 mg. dose and the similar interesting observation that some patients, for unknown reasons, require doses as large as 50 mg. in order to show definite clinical improvement. To many clinicians these may seem to be relatively enormous amounts of the pure vitamin to administer. It is pertinent to point out that the results are similar to those obtained with experimental animals. For example, the minimum amount of vitamin B₁ required to cure a pigeon and keep it free from the critical symptoms of advanced B₁ deficiency for at least three days is from three to five times the daily minimum for maintenance of weight. In order to permit rapid restoration to normal body weight and well being, the bird must receive from ten to twenty or more times the daily minimum for maintenance of weight. Assuming that such a relationship holds for man and taking for calculation the daily requirement of the average man as suggested by Vorhaus and his associates,¹³ namely, 1 mg. of thiamin chloride, one should expect precisely the results reported by Goodhart and Jolliffe³⁶ and by Weiss.³⁷

In view of what is known about the ready excretion of vitamin B₁ through the kidneys, it seems to me that the clinician must for the present necessarily steer between the one extreme of giving such small daily doses that the patient can improve only very slowly and the other extreme of giving so much (particularly by the parenteral route) that a large part is lost through the kidneys before the tissues can properly absorb and store it. Until studies have been made of the capacity of both the deficient and the normal organism to store vitamin B₁ administered in various ways under properly controlled experimental conditions, one cannot say what

are the largest effective yet economical doses of the pure vitamin to use in clinical work. As soon as chemical methods have been perfected, permitting prompt analysis of the urine and the blood for their vitamin B₁ content, these important studies can and should be performed. In view of the activity on this problem in many laboratories, no doubt one may confidently expect soon to have the desired chemical tools for this work. In addition to yielding the information desired with respect to the best doses to use clinically, such studies should also lead to a clinical function test by which the clinician may not only confirm his impression that the patient is suffering from serious vitamin B₁ deficiency but may even detect moderate deficiency, which might be called "vitamin B₁ subnutrition." It is my belief that such researches will reveal vitamin B₁ subnutrition to be sufficiently common to warrant serious attention on the part not only of the practicing clinician but of all students of preventive medicine, public health and nutrition. The condition, if found, could be corrected readily by improvement of the diet.

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF
THE FOLLOWING ARTICLE.

HOWARD A. CARTER, Secretary.

PHYSICAL THERAPY IN THE TREATMENT OF FRACTURES

FRANK D. DICKSON, M.D.

KANSAS CITY, MO.

Widespread mechanization of industry, the increase in the employment of machinery in agriculture and the tremendous growth in the use of the automobile have completely changed the fracture picture in the United States in recent years. This change has been in two respects: (1) There has been a great increase in the number of fractures which occur annually; (2) there has been a marked increase in the number of serious fractures. The increase in the number of fractures is traceable to the greater opportunity for suffering trauma likely to cause fracture; the increase in the number of severe fractures is ascribable to the severe damage which results from the type of violence which machinery inflicts. As a consequence of these factors, the fracture problem today must be considered as having two aspects: a medical aspect which includes the recognition, reduction and immobilization of fractures, and an economic aspect which includes the length of time consumed in recovery, as measured by the period over which the individual is disabled or restricted in activity, and the final result, as measured by permanent residual disability. The effectiveness of fracture treatment today, then, cannot be based solely on securing union of the fractured bone or bones, for the rapidity with which the individual is returned to work and the extent to which function is restored must also be taken into consideration. Formerly, treatment of a fracture consisted in applying a splint and leaving it to nature to complete the cure; today, when we are dealing with more serious and more complicated fractures than in the past, a successful end result is dependent not only on adequate immediate treatment of the fracture but also on carefully planned and supervised after-care. Both of these

requisites are necessary to meet the demands which the management of fractures today make on those who aspire to treat them and secure end results which will meet the critical judgment of public opinion and compensation commissions.

As this contribution deals with physical therapy as applied to fracture treatment, the immediate treatment of fractures may be briefly dismissed. It should suffice to say that at the present time it is generally conceded that a fracture should be treated as a surgical emergency and reduction under an anesthetic, local or general, carried out at the earliest possible moment and adequate fixation immediately applied. The reasons for this position are quite evident: immediate reduction minimizes local trauma and so cuts down the amount of traumatic exudate and infiltrate which accompanies any injury; it reduces to a minimum the undesirable muscle spasm always present; it favors the early reestablishment of blood and lymph circulation so important to healing. Following reduction, adequate splinting is necessary to insure continued maintenance of reduction and preservation of the conditions which make for rapid and complete healing.

The proper after-care of a fracture in the main consists of maintaining fixation of the fractured bone or bones until union has occurred, the early restoration of normal circulatory efficiency in the involved region and the building up of muscle tone and power so that normal use may be resumed at the earliest possible moment. Physical therapy, properly and intelligently employed, can be of inestimable service in this period of after-care in hastening recovery, but it is equally true that if physical therapy is used as a part of a routine without a true understanding of its purpose it may be a detriment rather than a help and even actually prolong the period of convalescence by inculcating in the patient a belief that recovery is to be attained by physical therapy alone and without effort on his part.

In order that physical therapy may be intelligently used in the treatment of fractures, it is necessary that its purposes and aims be clearly defined and recognized. Briefly stated, these are (1) promoting the early absorption of hemorrhage and traumatic exudate; (2) relaxation of muscle spasm to relieve pain and discomfort; (3) the reestablishment of normal circulatory conditions in the affected extremity, blood stream and lymphatics, which insures a more rapid and complete healing of the fracture; (4) building up in the muscles of the extremity that tone and flexibility so necessary to normal use. These effects, as has been emphasized by Clay Ray Murray,¹ are brought about by physical agents acting on the neuromuscular and neurovascular reflex mechanisms and through the stimulation of muscles by physical means or voluntary action.

Broadly speaking, there are four basic forms of physical therapy which may be employed in the treatment of fractures to accomplish the purposes catalogued; they are heat, massage, exercise and muscle stimulation. The first two of these secure their effect by bringing about muscular and vascular relaxation; the third and fourth are of chief importance in promoting venous and lymphatic flow and preparing the muscles to resume their normal active role as soon as use may be safely permitted.

1. Murray, C. R.: *Surg., Gynec. & Obst.* 56:479 (Feb., No. 2A) 1933.

HEAT

Heat as a physical agent may be applied in a number of ways such as by a therapeutic lamp, diathermy, electric pad and as radiant heat by the use of ordinary light bulbs set up in a cradle. Heat, to bring about the best results, should be employed at low intensity and over a considerable period. The most important effects secured from heat are analgesia, relaxation of muscles, relief of spasm and vasodilatation, and the longer these effects are maintained within reason the more productive they are. Heat of high intensity which produces a marked erythema cannot be tolerated long and is decidedly less beneficial.

MASSAGE

Massage has been described as the scientific manipulation of the soft tissues of the living body for therapeutic purposes. Massage is effective when applied by a trained person in a scientific manner; there is a vast difference between the skilled manipulation of a trained physical therapist and the rough and ready methods of the Turkish bath attendant or gymnasium rubber. Properly given, massage stimulates the nerve endings and activates sensory impulses of a wide variety which are important in relaxing muscular and vascular spasm and in relieving pain and discomfort. It also promotes the absorption of hemorrhage and exudate by improving blood and lymphatic circulation in a damaged extremity. The type of massage most useful in the treatment of fractures is light stroking massage; the movement should be slow, even, steady and always in the same direction; that is, lengthwise of the part in the direction of venous circulation. It should be remembered that massage employed to get rid of hemorrhage and exudate and reduce swelling acts by bringing about improved circulatory conditions and does not rub the exudate out of the part by pressure and force. Although all authorities do not agree, it is my opinion that light and very gentle kneading may also be used to advantage in fracture cases; such movements stimulate the intramuscular circulation and improve muscle tone.

MUSCLE STIMULATION

Muscle contractions may be produced by voluntary effort or by electrical stimulation. Voluntary contraction of muscle groups is incomparably superior to any form of artificial stimulation. Unfortunately, however, it is possible to utilize voluntary muscular activity in the treatment of fractures only to a limited extent until union is sufficiently strong. A very useful amount of voluntary contraction can usually safely be permitted and encouraged in most fractures earlier than is generally recognized under proper conditions of immobilization. Such limited voluntary use is made possible by employing fixation (traction or hinged splints) which holds the fractured bone or bones securely but permits the guarded use of adjacent joints, by the use of molded plaster splints instead of circular plaster dressings and also by having the patient "set" the muscles of the injured extremity a number of times each day; such "setting" of the muscles can be carried out even when the limb is completely encased in a plaster dressing. The extent to which muscle tone and flexibility can be maintained by carefully supervised daily exercise under proper conditions of fixation is often surprising.

Muscle stimulation by electrical stimulation, while not as satisfactory as active exercise, is nevertheless a useful

therapeutic aid for maintaining muscle tone. Pember-ton² has shown that whereas lactic acid is produced by contraction of muscles following volitional effort it does not arise at least in significant amounts as the result of stimulation of the muscle by faradic current. It is therefore probable that no form of electrical stimulation can be expected to produce the same type of muscle contraction as that which results from voluntary use. To avoid painful contraction some form of sinusoidal current may be used. The Council on Physical Therapy will furnish a design for making a faradic sinusoidal coil. This coil produces a sinusoidal current which will give graduated muscular contraction as described by Bristow and Smart. The value of these contractions is primarily the increase in circulation in the muscle. When electrical stimulation is utilized to bring about muscle contraction, it should be painless and not cause muscle spasm; for, when pain and spasm are produced, harm rather than good results.

Of equal importance with the measures used for applying physical therapy is their use at the proper time. Too often physical therapy is looked on as the final step in fracture treatment, as an agent to be used to restore function to atrophied muscles and stiffened joints which have been rigidly immobilized for weeks in a fixation dressing. While occasionally fractures are encountered in which the application of physical therapy is impossible until union is complete, to wait so long in the vast majority is losing valuable time and unduly prolonging convalescence. Theoretically, physical therapy may be used advantageously in all three stages into which fracture treatment is divided, the reduction period, the postreduction period, and in after-treatment.

THE REDUCTION PERIOD

While unquestionably massage and elevation may be used with advantage to reduce swelling and quiet muscle spasm preceding reduction and the application of definitive splinting, to carry out such measures in a routine way demands a special setup and personnel which is rarely available. Practically, then, physical therapy can play but a minor role in the reduction period. However, when for any reason it is impossible to proceed with the immediate reduction of a fracture, even if the delay is but a few hours, heat and gentle massage may be used to advantage. When fractures are accompanied by severe trauma to the surrounding soft parts with extensive hemorrhage, and reduction, open or closed, must be delayed for several days, heat and massage may be used with considerable benefit to improve the condition of the soft parts and permit the application of definitive treatment much sooner than would otherwise be possible.

THE POSTREDUCTION PERIOD

In the postreduction period physical therapy should assume a very important role in fracture treatment, but unfortunately it is during this period that it is most neglected. It is in the immediate postreduction period that exudate and hemorrhage which will become organized into scar tissue about the muscles, tendons, vessels and nerves and interfere with muscle action, normal circulation and joint movement can largely be removed by restoring as early as possible normal circulatory efficiency to the part. The stiffness, soreness and impaired function following a fracture are due in large part to

2. Handbook of Physical Therapy, page 73.

such scar tissue and its removal or at least reduction to a minimum lessens the discomfort incident to restoring function and materially shortens the period of convalescence. Furthermore, in the light of recent investigations, clinical and experimental, it seems clearly established that delayed union and nonunion are in the main traceable to interference with circulation at the fracture site so that early restoration of circulatory efficiency is our best safeguard against these catastrophes.

It is quite true that the application of physical therapy at this time is often difficult because the part is encased in a fixation dressing, but by the use in both bed and ambulatory cases of traction, which allows ready access to the part for physical therapy, through apertures in plaster dressings, by the use of hinged splints which allow movement in adjacent joints without disturbance of the fracture site, by the use of open splinting and by daily "setting" of the muscles, it is usually possible in most fractures to use heat, massage and muscle contraction throughout the period of fixation to the great advantage of the patient. So-called open splinting has in recent years been used more and more in the fixation of fractures; this permits the employment of physical therapy to a very satisfactory extent. By open splinting is meant using anterior or posterior or lateral molded plaster splints to replace circular plaster dressings when possible; as, for example, in Colles fractures, fracture of the patella and fractures of the ankle. Such splints afford ample exposure for physical therapy without disturbing the fracture. If a circular plaster dressing is used, it may be bivalved and the halves removed alternately for the application of physical therapy.

In addition to "setting" muscles in this postreduction period, active muscle contraction may be encouraged in several ways. Even with the forearm and arm encased in a plaster cast, if the fingers are free, the patient by squeezing and relaxing the grip on a rubber sponge can exercise the forearm and arm muscles extensively. Under the same conditions the shoulder and arm muscles will retain a large part of their tone and power if the shoulder joint is exercised regularly each day instead of holding the arm continually suspended and immovable in a sling. In Colles fracture, too often the elbow and shoulder joints are not moved and exercised, with the result that atrophy of the arm and shoulder muscles and limitation of movement in the elbow and shoulder joints prolong recovery while these avoidable conditions are being corrected. In leg fractures, systematic knee and hip exercises should be carried out each day to maintain muscle tone and strength in the thigh and hip muscles so that the extremity will be better prepared to function when weight bearing is permitted. In these ways and others which naturally suggest themselves, muscles and joints may be kept active and the general strength of an extremity maintained in a state of reasonable efficiency.

THE PERIOD OF AFTER-TREATMENT

It is in the period of after-care that physical therapy is most generally used in fracture treatment. It is unfortunate that it is so frequently improperly used. The objective sought for in the after-care of a fracture is the restoration of normal use to the injured part after union of the fracture is complete and splints and restraints have been removed. The restoration of the ability to use the damaged limb normally or at least

satisfactorily is possible only when muscles are active and joints movable. Muscle tone, flexibility and power can be built up only by progressively increasing active use of the muscles by the patient; a joint stiff or with limited motion can become movable and reasonably useful only through the establishment of muscular control of the joint by the patient. It should be clearly understood that the range of passive movement which can be obtained in a joint is no criterion of its usability, since only that degree of movement which the patient can control is usable. Furthermore, until voluntary control of joint motion is established, ankylosis or serious impairment of the range of joint motion of a more or less permanent character is possible. The role of physical therapy in the after-treatment of fractures may be stated then to be helping the patient to regain voluntary use of the muscles and voluntary control of impaired joints of the injured extremity. Heat, massage and muscle stimulation can reduce swelling, can decrease pain, soreness and stiffness in weak and degenerated muscles, can improve vascular and lymphatic circulation, can stimulate neuromuscular and neurovascular impulses, can in brief make it easier for the patient to use the impaired part and build up voluntary control, but they cannot make him well. The patient, in the last analysis, is master of his fate, and physical therapy is but the tool which enables him to carve out his recovery with the least discomfort, the greatest speed and to the fullest extent.

In seeking to help a patient to regain voluntary control of the muscles and joints following a fracture, heat and massage should be used to loosen up and render more pliable muscles and so reduce the stiffness and pain incident to attempts at movement. The movements which are used should be designed to bring about normal action of the joint in the most natural manner. Having the patient go through the motions of brushing the hair in elbow fractures, driving nails with a light hammer in fractures of the wrist, turning a door handle in fractures of the forearm, and reaching for objects placed at a gradually increased height in shoulder fractures illustrate the methods which may be used to encourage the patient to use the extremity in a normal manner.

While emphasis has been laid on the basic forms of physical therapy, heat, massage, and muscle stimulation, it should be stated that there are varieties of these basic forms which may be used with satisfactory effect. Contrast hot and cold baths, the whirlpool bath and the hot paraffin bath may be mentioned as examples. The use of balanced weights on pulleys and various devices which encourage the patient to use joints with a restricted range of movement are most helpful. Also many types of apparatus have been devised which are helpful and enable treatment to be given efficiently and comfortably. Too often such apparatus is expensive and complicated and its use is but vaguely understood, so that it is employed according to directions given in a printed pamphlet which accompanies it from the manufacturer, who rarely underestimates what it will do or the number of conditions it will benefit. By all means let us be ready to take advantage of any advances and improvements which science offers, but let us demand that the criterion of the therapeutic effect expected from any piece of apparatus be a scientific and medically correct one and not an empiric one determined by its maker. Helpful as apparatus may be, it

does not eliminate the element of judgment in how and when it should be used, nor can we blindly accept the statement of the maker as to its therapeutic effect. The accepted list of the Council on Physical Therapy of the American Medical Association is a reliable guide to apparatus which performs as claimed.

OCCUPATIONAL THERAPY

Any discussion of physical therapy in the treatment of fractures would be incomplete without mention of occupational therapy. Occupational therapy is a method of rehabilitation which is most useful in the treatment of fracture patients.

Occupational therapy is chiefly valuable because it supplies a real incentive for the patient to use the impaired part. A definite task is given him to perform and in spite of himself he becomes interested in completing it, with the result that he is inspired to renewed effort and unconsciously develops the attitude of mind which is necessary for recovery. Unfortunately, this form of physical therapy requires trained attendants and some apparatus so that its use is largely restricted to centers where these requisites are available; ingenuity, however, may work out simple tasks which may replace apparatus for rehabilitation training. Light carpentry, which requires the use of hammer, plane, saw and sandpaper, is available everywhere and is a useful type of occupational therapy for restoring function in the upper extremity. Gardening, painting and a variety of other simple occupational pathways may be utilized to improve joint motion, increase muscle strength and control, and above all build up the patient's morale and help him progress from the passive role of a recipient of physical therapy to an active role of one who is giving himself physical therapy. Occupational therapy is a very useful way of overcoming the subconscious resistance of the patient to normal use of an injured part for fear he will suffer a relapse. It is often a useful bridge over the hiatus between return of use and return to normal life and activity.

AMOUNT TO BE USED

Finally, some mention should be made of the amount of physical therapy which may be used. There is but one reliable guide as to whether physical therapy is being given properly and that is the reaction of the patient. Physical measures may be used up to the point of pain tolerance provided the painful reaction subsides within an hour or two. Physical therapy which produces painful reaction and muscle spasm that persists until the next treatment indicate too forceful or too prolonged treatment and both amount and duration must be reduced; persistence can lead only to resistance on the part of the patient, slowing up of recovery, and a disappointing result.

CONCLUSION

In the treatment of fractures physical therapy has a most important role. Used intelligently in the post-reduction period it will reduce scar tissue, infiltration of muscles, tendons and joints, maintain a satisfactory state of the circulatory apparatus and greatly reduce the period of after-treatment. Properly employed in the after-treatment it will help the patient to do his part, which is building up that voluntary active use of the impaired extremity which alone can restore function, hasten his recovery and complete the cure.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

- (1) NUTRADIET APRICOTS PACKED IN WATER
- (2) NUTRADIET PEELED APRICOTS PACKED IN WATER

Distributor.—The Nutradiet Company, a subsidiary of S & W Fine Foods, Inc., San Francisco.

Description.—Canned peeled and unpeeled apricots packed in water without added sugar.

Manufacture.—Tree-ripened apricots are inspected, washed and mechanically graded. The pits and blemishes are removed by hand, and fruit for the 8 ounce pack is cut and is peeled by submersion in a hot solution of caustic soda. The fruit is packed in cans and water is added. The cans are exhausted in the presence of steam, sealed and processed in boiling water.

Analyses (submitted by manufacturer).—(1) Moisture 90.4%, total solids 9.6%, ash 0.43%, fat (ether extract) 0.07%, protein (N \times 6.25) 0.5%, crude fiber 0.3%, carbohydrates other than crude fiber (by difference) 7.6%, total acidity 0.7%. (2) Moisture 92.2%, total solids 7.8%, ash 0.38%, fat (ether extract) 0.06%, protein (N \times 6.25) 0.4%, crude fiber 0.3%, carbohydrates other than crude fiber (by difference) 6.0%, total acidity 0.7%.

Calories.—(1) 0.33 per gram; 9 per ounce.

(2) 0.26 per gram; 7 per ounce.

Claims of Manufacturer.—For diets in which sweetened fruit is proscribed.

CELLU BRAND CARROT JUICE

Distributor.—Chicago Dietetic Supply House, Inc., Chicago.

Description.—Juice expressed from carrots packed without added water, salt or sugar.

Manufacture.—Selected mature carrots are washed, cooked, peeled, inspected, trimmed by hand, rinsed in cold water, ground to a fine pulp and pressed through a cloth. The resulting juice is strained, and filled into cans. The cans are heated, sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 93.2%, total solids 6.8%, ash 0.3%, fat (ether extract) 0.2%, protein (N \times 6.25) 0.3%, reducing sugars as dextrose 1.6%, starch 2.6%, crude fiber 0.03%, carbohydrates other than crude fiber (by difference) 6.0%.

Calories.—0.27 per gram; 8 per ounce.

MRS. PALEY'S BABY FOOD— STRAINED SQUASH

Manufacturer.—Paley-Sachs Food Company, Houston, Texas.

Description.—Canned, sieved squash, slightly seasoned with salt.

Manufacture.—Yellow Crook Neck squash is inspected, washed, scrubbed with soft brushes and trimmed. The unpeeled squash is cooked under pressure without water until tender and strained in an atmosphere of steam. Salt is added and glass jars are filled, vacuum sealed and heat processed. No spray is used during the cultivation of the squash.

Analysis (submitted by manufacturer).—Moisture 90.5%, total solids 9.5%, ash 0.8%, fat (ether extract) 0.4%, protein (N \times 6.25) 1.4%, reducing sugars as dextrose 5.2%, sucrose none, crude fiber 0.5%, carbohydrates other than crude fiber (by difference) 6.4%, iron (Fe) 0.0015%, phosphoric acid (P₂O₅) 0.094%, phosphorus (P) calculated 0.041%, calcium (CaO) 0.029%, calcium (Ca) calculated 0.021%.

Calories.—0.35 per gram; 10 per ounce.

SATURDAY, SEPTEMBER 10, 1938

THE USES OF ANIMAL EXPERIMENTATION

The conservative attitude of the medical profession has both good and bad aspects—good when it refuses the use of untried drugs and unproved methods of therapy, bad when it permits medical progress to be attacked and maligned without defending itself. This attitude permits the public to be deceived concerning medical progress and sometimes causes the sick to seek relief from undependable sources which promise help. THE JOURNAL, by its continual exposure of "quack" medicines and falsely claimed "cures," has for many years done a great service to the public as a whole. More difficult to combat than such deliberately fraudulent claims, however, is the destructive work of the small but vociferous group opposed to experiments on animals. Their "crusaders" each year spend large sums of money in an attempt to stop all experimental work in the biologic sciences. In spite of the proved facts concerning the whole science of bacteriology, learned almost entirely through animal investigation, they claim that no good has come through man's utilization of animals in laboratory study.

The antivivisectionists refuse to recognize the great and continuous fall of the death rate in the infectious diseases, the remarkable extension of life¹ since the discovery of bacteriology and the beneficent progress of modern surgery as related to animal investigation. True, if their children acquire diphtheria they may use antitoxin, and if they develop appendicitis they may seek out a surgeon, but the relation of these therapeutic agents to research on animals is disclaimed. With these people argument and elucidation of the facts serve little purpose, for they twist the truth, misquote medical men now dead, and play on sentiment, not reason.

At present opponents of experiments on animals are proposing and advocating the so-called Humane Dog Pound Initiative in California, which will be voted on by a referendum in November. This cleverly constructed piece of legislation is apparently aimed against

unnecessary suffering of dogs; actually it will make further animal investigation in the state of California difficult and hopelessly expensive. Such legislation, if passed, will seriously hamper further laboratory investigation in every state. Proper education of the public in (1) the methods of animal investigation and (2) the advantages that have accrued to the people from animal investigation should do much to bring about its defeat.

The articles now appearing in the *Country Gentleman* written by Paul de Kruif are a splendid assistance in this important task. In these articles de Kruif has exposed not only how much man has benefited but how much the animals themselves have benefited from laboratory investigation. The tremendous decrease in Texas fever of cattle, hog cholera, bovine tuberculosis and foot and mouth disease are striking examples of how the use of a few animals in laboratory investigation has lessened or completely done away with the suffering of hundreds of thousands of animals. De Kruif has sharply emphasized this advantage by stating the tremendous financial saving to our farmers. Naturally man cannot control human disease as completely as animal disease. The article in the September issue of the *Country Gentleman* depicts the possibilities for comfort and longevity which may follow the acquisition of exact knowledge through animal investigation. In succeeding issues the advantages which have accrued to man through similar animal experimentation will be made public.

This service to the continuance of medical research deserves recognition by the medical profession. Every physician may aid by calling the attention of patients and friends to these masterful statements.

ANALYSIS OF FACTORS IN THE DECLINE OF TUBERCULOSIS

The mortality from tuberculosis has declined from about 30 per 10,000 of population to 5 or 6 in the last fifty years. What are some of the possible factors which have brought about this decline? In an analysis Wolff¹ distinguishes (1) a specific factor, (2) a hereditary factor, (3) a social factor, (4) a population factor and (5) the medical prophylactic factor.

The tubercle bacillus probably comes in contact with the entire population in urban areas; hence the bacillus alone is not sufficient to produce clinical illness, still less an epidemic. The decrease in mortality cannot be attributed to a natural protective inoculation, for, as Neufeld of the Robert Koch Institute says, natural inoculation with tuberculosis produces a limited immunity which is only relative and rapidly diminishes. The slow course of the disease clearly shows that the infection does not carry with it specific immunity. The relative immunity of which Neufeld spoke may be

1. Life expectancy in the United States increased from 46 to 61 from 1912 to 1937.

1. Wolff, George: Tuberculosis and Civilization: Part II. Interpretation of the Etiological Factors in the Epidemiology of Tuberculosis. *Human Biology* 10: 251 (May) 1938.

broken when resistance is reduced, as shown by the rise in the mortality rate during the World War.

A constitutional factor does play a part in tuberculosis mortality. In the same family under almost identical environment one may see some children succumb to tuberculosis while others do not. Inherited factors produce a constitution that plays an important part in the pathology of most diseases. A precise differentiation of what qualities predispose to tuberculosis or what kind of constitution affords protection against it has not been determined. The figures in Pearl's investigation show that, where one or both parents were actively tuberculous, virtually three fourths of the nontuberculous offspring have been in just as close contact with open cases as their brothers who acquired the disease. Some writers have revived the theory of selection by mortality, a view which Pearson used long ago to explain the decline in tuberculosis mortality. Natural selection by the early death of the tuberculous does not sufficiently explain the epidemic course. The reproductive powers of the tuberculous in the majority of cases continue nearly until death or the usual age and thus they maintain their stock.

Among German writers, Fritz Lenz came to the conclusion that blond types are less affected by tuberculosis than brunets. Lenz writes that tuberculosis has been a factor in producing in northern Europe, which is poor in sunlight, the blond clear-skinned type, while in the southern part, where the blond type is more susceptible to malaria, there has been a change in favor of brunets. Thus Lenz explains the frequency of blond Jews in central Europe by the selective action of tuberculosis in favor of blonds. Wolff believes that more exact knowledge of the epidemiologic data suggests that the lower mortality of Jews from tuberculosis is correlated with economic factors.

The social factor is probably the most important factor in the downward trend of tuberculosis. It is so important and complex that Wolff divides it into elements. The factor of economic well being can be analyzed into such parts as housing, occupation, nutrition, size of family and hygienic education, all of which are related. National nutrition is of great importance. The mass experiments in nutrition provided by the World War speak eloquently on this point. As early as 1915 in England and Germany the tuberculosis mortality rate was higher than in 1914. If nutrition has the main role in increasing tuberculosis mortality during the World War, improvement in nutrition over the last fifty years has had a part in the decline.

Various investigators have shown that occupation plays a part in tuberculosis mortality. In the standardized mortality figures in an occupational study among males in England and Wales during 1921-1923, the tuberculosis mortality for agricultural workers was found to be 96, for brewers 115, for bricklayers 127, for cotton spinners 175, for shoe factory workers 298 and for tobacco factory workers 326. Shoemakers are

not exposed to any particular hazard and yet they show a high mortality. That is because persons enter this occupation who are physically unfit for other occupations. For the same reason bricklayers have a relatively favorable mortality. Bricklaying is not an occupation for men of poor physique. In spite of the risks of industrial work, the average tuberculosis mortality in industrialized states is lower than it is in the agricultural states, where there is a lower standard of hygiene and of living. The better social, economic and hygienic conditions in the industrial states, together with better medical treatment, probably is the basis of this difference. Industrialization has brought with it not only dust and industrial diseases but also an elevation of the national well being which much overcompensates the disadvantages of industrial work.

Closely connected with industrialization has been a biologic change in the industrialized states reflected in a decline in the birth rate. With a smaller family the average income per head increases whether the wages are increased or not. The decline in birth rate necessarily effects a change in the structure of the family. Reduction in size of the family increases the proportion of the family budget available to each member. There is even a direct influence on the possibility of infection, for the virus in a smaller family has a smaller field of operation.

In a study of the mortality of young adults from tuberculosis, Bradford Hill concluded that the level of mortality in the different rural districts was influenced by the movement of the population, particularly internal migration. The urban districts which have attracted young people showed a decrease in mortality, while the districts that have lost population tended toward increased mortality in young adults. The success of medical treatment and medical care of people generally forms a part of the social environment, and practice of medicine in the field of tuberculosis ranks high.

Thus a critical examination of statistics shows that of all the factors influencing the epidemic march of tuberculosis the decisive factors are the socio-economic and sociobiologic, combined with changes in the standard of living brought about by industrialization. The tuberculosis mortality rate has fallen greatly because particular strata of the working classes are now as well to do as or even better off than many of the middle classes. Compared with these the natural environment—climate, sunshine, soil—is of minor importance.

A national campaign against tuberculosis, in Wolff's opinion, should have as its goal further improvement of the social environment so that persons infected by tuberculosis will not become victims of the disease. It should never be the task of the physician to breed human beings refractory to tuberculosis, ignoring all other mental and physical hereditary qualities. Further extension of the process that has been at work in the last fifty years may yet bring tuberculosis to the vanishing point.

ETHICS OF AMERICAN BAR ASSOCIATION GOVERNING SIMULTANEOUS PRACTICE OF MEDICINE AND LAW

The Committee on Professional Ethics of the American Bar Association in a recent opinion¹ holds that a person legally authorized to practice law and medicine may practice the two simultaneously without violating the canons of professional ethics of that association but that he must recognize in every case the particular capacity in which he is acting. In a previous opinion² the committee held unethical a statement on a lawyer's letterhead announcing that he was a specialist in "medical-legal" law.

In its recent opinion the committee says that a person practicing law and medicine simultaneously offends against the canons of professional ethics if in correspondence connected with his practice of either profession he uses a letterhead that contains the two appellations "attorney at law" and "doctor of medicine" or shows that he has the degrees of LL.B. and M.D. or contains the phrase "medical jurisprudence." In fact, in the opinion of the committee a lawyer cannot ethically place on his professional letterhead any indication of any degree conferred on him. A lawyer-physician who is establishing offices for the practice of law and medicine jointly cannot, in the opinion of the committee, without violating the canons of professional legal ethics, send out announcements of the establishment of such offices at a specified address for the practice of both law and medicine. A person practicing law and medicine coincidentally cannot ethically send announcements even to members of the legal profession stating that he is specializing in medical jurisprudence unless he is offering that specialized service directly and exclusively to lawyers. A lawyer engaged in "a specialized legal service" directly and exclusively to other lawyers may ethically publish in legal periodicals and like publications a brief dignified notice of that fact, in language indicating that it is addressed to lawyers alone, when such a notice will afford convenient and beneficial information to lawyers desiring to obtain such services. The Committee on Professional Ethics, however, refrains from expressing any opinion as to whether a lawyer acting as counsel to other lawyers in matters involving a knowledge of medical jurisprudence is or is not "rendering a specialized legal service" within the meaning of this rule. It is not inconsistent with the canons of legal ethics, in the opinion of the committee, for a lawyer who is opening offices for practice as a lawyer and as a physician simultaneously, to send separate announcements of the opening of such offices to those with whom he has previously established personal relations within the meaning of the canons of legal ethics, but the announcement of the opening of his law office and the announcement of his opening of an office

for the practice of medicine, if sent to the same person, should not be sent under the same cover.

The opinion rendered in the present instance was rendered in response to a request from a committee on professional ethics of a state bar association and pursuant to authority vested in the Committee on Professional Ethics of the American Bar Association to express its opinion concerning proper professional conduct when consulted by any member of the bar or by any officer or committee of a state or local bar association. The committee is authorized furthermore to consider on its own motion or on a complaint information as to the professional conduct of any member of the association and, after a hearing, to recommend to the Board of Governors the public or private censure, suspension or expulsion of an offending member. The board may censure, suspend or expel a member for cause. The published opinion of the committee in the present instance does not show whether disciplinary action has been taken or is contemplated in any specific case because of the misconduct of any member of the association.

Current Comment

NEUROSES AND SOCIO-ECONOMIC CONDITION

The effect of social conditions on the incidence of disease is well recognized. In a recent contribution Neustatter¹ reports three groups of fifty families studied to determine the role of socio-economic circumstances on the production of neuroses. The first group comprised poor working-class families in southeast London, picked at random. The second was chosen from the parents of children attending the council schools in southeast London but composed principally of small professional and clerical workers with modest incomes, and the third was a group of "well-to-do" families from a northwest London suburb of middle class and economically more comfortable than the other groups. The information was obtained from questionnaires directed to parents and from personal interview. The specific purpose was to determine whether there was any relationship between the socio-economic status of the parents and the frequency of various neuroses, including night terrors, depression, unsociability and aggressiveness. Although the dangers of the questionnaire method were fully recognized, the results appear to be significant. A clearcut physical difference between the two groups of poorer children and the "well-to-do" was noted: one third of the children in the poorer class showed "poor physique," and pallor and tired and lined facies were found practically only in the poorest group. In the poor group of fifty families, twenty were badly housed and thirty had insufficient money for food. Only 20 per cent of this group however were nervous and 56 per cent were not, as compared with 30 per cent nervous and 36 per cent not in the fifty "well-to-do"

1. Opinion 183, May 10, 1938, American Bar Association Journal 24: 673 (Aug.) 1938.

2. Opinion 159, May 5, 1936, American Bar Association Journal 22: 503 (July) 1936.

1. Neustatter, W. L.: The Effect of Poor Social Conditions in the Production of Neuroses, *Lancet* 1: 1436 (June 25) 1938.

families. It was concluded therefore that poor social conditions are not in themselves a direct determinant of nervousness in children. Furthermore, case histories were obtained showing that even extremely bad social conditions leave children unaffected psychologically provided the psychology of the home situation is good. Social circumstances do at times affect children through the parents but surprisingly little, and then generally when the parents are already nervously predisposed. A statistically significant relationship between the presence of a worrying disposition in the parents and the presence of anxiety and a tendency to worry in the children irrespective of class was demonstrated. Poverty, therefore, seems to decrease rather than to increase the incidence of many neuroses.

ACCIDENT STUDIES IN KANSAS

As lives have been saved from disease they have been sacrificed to accidents. The modern safety movement is an answer to the challenge of accidental death and injury. Among the most comprehensive studies of accidents have been those carried out and published annually by the board of health of the state of Kansas.¹ The Kansas State Board of Health has prepared a special form for reporting accidental deaths. This work was begun in 1932. The current report for 1937 is the sixth annual publication of the data procured through these special reports. The reports are procured with the assistance of sheriffs, police officers, physicians, coroners and others. The resulting data are as complete a record of accidental deaths as is available on a state-wide basis anywhere. Accidents ranked fifth in causes of death in Kansas, preceded only by heart disease, cancer, cerebral hemorrhage and chronic nephritis. In 1934 they ranked fourth in importance but for the last three years have ranked fifth, with a total of 1,492 accidental deaths reported in 1937, the lowest number since 1932. The death rates per hundred thousand of population have varied from 54.6 in 1932, the first year of the intensive study, to a high of 68.3 in 1936 and a rate of 57.3 in 1937. The lowest rate during the six years was 56.1, in 1933. The decline of 339 during 1936 was accounted for by a reduction of ninety-five in automobile deaths, or around 20 per cent, and of 244 in all other accidents, or about 25 per cent. The largest number of deaths was due to automobiles (447), the second to falls (367), the third to drowning (eighty-eight), the fourth to burns and the fifth to railroad trains but involving automobiles. Other important causes were trauma by firearms, excessive heat, electric currents, poisonous gases and other accidental poisonings. The report contains extensive tabulations classifying accidental deaths by causes, by years, by months, by occupations and by counties. Lists of unusual fatal accidents are interpolated in the report and are interesting as evidence of two common underlying causes of all accidents, namely carelessness and panic. The rising toll of accidental deaths bids fair to eclipse the saving made through advances in medicine and public health.

1. Kansas Accidental Deaths, 1937, published by the Kansas State Board of Health; 16 pages; planographed; gratis to health or safety officials.

Association News

SPECIAL SESSION OF HOUSE OF DELEGATES SEPTEMBER 16, 1938

All meetings of the special session of the House of Delegates of the American Medical Association to be held in Chicago September 16 will be in the Red Lacquer Room at the Palmer House. Delegates who wish to have accommodations at the Palmer House should make reservations immediately. The first meeting of the House of Delegates will be called to order at 10 a. m., Chicago daylight saving time, Friday, Sept. 16, 1938.

STATE SECRETARIES AND EDITORS TO ATTEND SPECIAL SESSION OF HOUSE OF DELEGATES

The Board of Trustees has requested the secretaries of the constituent state medical associations and the editors of state medical journals to attend the special session of the House of Delegates of the American Medical Association to be held at the Palmer House in Chicago September 16.

The regular Annual Conference of Secretaries of Constituent State Medical Associations will not be held this year.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Proposed Activities of State Association.—An outline of medical activities in Alabama is presented in a letter recently mailed to members of the state medical association by the president, Dr. Seale Harris, Birmingham. It is hoped that the monument to Dr. James Marion Sims, pioneer surgeon (1813-1883), approved at the last annual session of the association, will be ready for unveiling at the next meeting in April. An artist has been employed to prepare the model for and to supervise the construction of the monument, which will be in the form of a bronze statue to be placed on the state capitol grounds. Members are urged to participate actively in the movement to establish a four year medical school in Alabama and to cooperate to the fullest extent in the survey on medical care now under way by the American Medical Association. An appeal is also made to each physician to bring new members into the society and to take complete advantage of the opportunities offered by the society by attending scientific sessions and by use of facilities. Pointing out that each of the sixty-seven counties in the state has a full time health officer, Dr. Harris emphasizes the need and expense of an adequate health department and recommends that physicians throughout the state discuss with the representatives of the state legislature the necessity for continued support in this field.

CALIFORNIA

Health of Mexicans in California.—The state department of health has published a statement on the health of Mexicans in California over a ten year period. Because the number of Mexicans in the state now is not known, the figures noted in the 1930 federal census are used: 368,013 Mexicans, or 6.5 per cent of the total population of the state, which at that time was 5,677,251. In 1930 there were 14,472 Mexican births registered, 17.2 per cent of the total number of births in the state (84,382); in 1933 there were 10,857, or 14.4 per cent of the total, and since that time there has been an annual increase, the total reaching 12,173 in 1937. During the ten years 1928-1937 there has been an annual average of 12,700 Mexican births in this state, or 15.2 per cent of the total. The infant mortality rates among Mexicans are particularly high; during the ten year period one third of all infant deaths in California were in Mexicans, giving an annual average of 1,556 of these deaths. Typhoid and diphtheria are highly fatal to Mexicans; 20 and 24 per cent, respectively, of all deaths in the state from these diseases during the past nine years were in Mexicans. Pneu-

monia and influenza caused 17 and 12 per cent, respectively, of all deaths among Mexicans; 22 per cent of all deaths were from tuberculosis, and 18 per cent of all deaths in childbirth from 1929 to 1937, inclusive, were among Mexican mothers.

DELAWARE

Nemours Foundation for Crippled Children.—Construction will begin in October on a new 100 bed hospital for crippled children within the Nemours Estate near Wilmington under the auspices of the Nemours Foundation for Crippled Children. The tentative date for the opening of the hospital is the fall of 1939, according to the *Delaware State Medical Journal*. Children up to the age of 16 years will be admitted to the hospital but may be kept for educational purposes to an older age if necessary. Carrying out the terms of the will of the late Mr. Alfred I. du Pont, the Nemours Foundation for Crippled Children was incorporated Sept. 2, 1936, with the following trustees: Mrs. Alfred I. du Pont, her brother Mr. Edward Ball, and Mr. du Pont's son-in-law Col. Reginald S. Huidekoper. A medical advisory board was appointed consisting of the following members:

Dr. Thomas R. Brown, associate professor of medicine, Johns Hopkins University School of Medicine, Baltimore, chairman.
Dr. Robert B. Osgood, John B. and Buckminster Brown, professor emeritus of orthopedic surgery, Harvard University Medical School, Boston, secretary.
Dr. Philip D. Wilson, clinical professor of orthopedic surgery, Columbia University College of Physicians and Surgeons, New York.
Dr. George E. Bennett, associate professor of orthopedic surgery at Johns Hopkins.
Dr. DeWitt B. Casler, associate in gynecology at Johns Hopkins.
Dr. William T. Graham, professor of orthopedic surgery, Medical College of Virginia, Richmond.
Dr. Beverley R. Tucker, emeritus professor of neuropsychiatry, Medical College of Virginia, Richmond.
Dr. Michael Hoke, Beaufort, S. C., formerly chief surgeon at Warm Springs Foundation, Warm Springs, Ga.

A four point program has been adopted by the advisory board: medical care of the crippled child, which begins with the construction of the new hospital; education of the crippled child; research on problems relating to the crippled child, and graduate instruction for persons interested in this field. Concerning the education of the crippled child, it is proposed, after the hospital is opened, to build several cottages, separate from the hospital, for the convalescent school children. A school building will be erected later. In the educational program emphasis will be placed on the vocational education of the child over 14 years of age. Following this training it is hoped to find permanent employment for these children. All types of training will be offered, the child's physical handicap to be the deciding factor. Primary and secondary school education will be given to the younger children. The research program will include both laboratory and clinical problems. The original laboratories will be for biochemistry and bacteriology with facilities for pathology. These will be staffed by a personnel particularly interested in research problems and a certain number of hospital beds will be available for the research division so that the clinical and laboratory work may be coordinated. For the coming year four research fellowships have been established in selected medical centers for the study of problems directly related to crippling diseases in childhood. Courses of graduate instruction in orthopedic work will be established as soon as warranted by the organization of the hospital and the institution at large. At the beginning only crippled children from the state of Delaware will be admitted; it has been estimated that there are about 200 in need of hospital care. According to the state medical journal, the chief difference between this and similar institutions is the emphasis on vocational education of the crippled child and on research. Dr. Alfred R. Shands Jr., formerly associate professor of surgery in charge of orthopedics, Duke University School of Medicine, Durham, N. C., was appointed medical director of the foundation in June 1937.

ILLINOIS

New Building for St. John's Hospital.—A new building to replace the central structure of the present St. John's Hospital, Springfield, is now under construction. When completed, the main part of the unit will be twelve stories high and cost \$1,200,000. The first floor will accommodate the physical therapy department, kitchens, coffee shop, pharmacy and central sterilizing department as well as the lobby and waiting rooms. The second to seventh floors will contain rooms and wards, while the eighth floor will be devoted to infectious diseases. The ninth floor will contain the septic surgical department, surgical dressing and specialists' departments, separate provisions being made for treatment of the eye and throat, dental work and bronchoscopy under both local and general

anesthesia. The operative floor is the tenth with laboratories on the eleventh. Solariums and storage rooms occupy the twelfth floor. The thirteenth and fourteenth floors cover only a small part of the building area and are used for the mechanical equipment. Rev. J. L. Gatton is director of the hospital.

Chicago

Coordinating Committee on Cancer.—The University of Chicago has appointed a committee on cancer to correlate its program of research and the clinical treatment of cancer. According to the announcement the creation of the committee, which will operate virtually as a cancer institute, was made necessary by the comprehensive nature of modern investigation of the disease. The new committee will correlate all basic research with the efforts of the clinical departments and serve as a clearing house for all the university investigators in nine departments; it will also advise the administration as to needs and policies of the general program. Members of the committee include:

Dr. Alexander Brunschwig, chairman of the committee.
Dr. Fred L. Adair, chairman of the department of obstetrics and gynecology and chief of staff of the Chicago Lying-In Hospital.
Dr. Percival Bailey, professor of surgery (neurosurgery) and neurology.
Arthur H. Compton, Ph.D., Charles H. Swift distinguished service professor of physics.
Dr. George F. Dick, chairman of the department of medicine.
William D. Harkins, Ph.D., Andrew MacLeish distinguished service professor of chemistry.
Dr. Paul C. Hodges, professor of roentgenology.
Thorfin R. Hogness, Ph.D., professor of chemistry.
Fred C. Koch, Ph.D., chairman of the department of biochemistry.
Ezra J. Kraus, Ph.D., chairman of the department of botany.
Dr. Dallas B. Phenister, chairman of the department of surgery.
Maud Slye, Sc.D., associate professor of pathology.
Dr. Paul E. Steiner, assistant professor of pathology, secretary.
Dr. Harry Gideon Wells, chairman of the department of pathology.

Announcement was also made that the university had received a total of \$11,750 in grants and gifts for work on cancer. Three grants totaling \$7,500 were from the National Advisory Cancer Council of Washington and will facilitate research on the influence of cancer on stomach secretions, research on hormones and on chemical substances in cancer tissues. The International Cancer Research Foundation made a grant of \$2,000. The Educational Association on Cancer has given the university \$2,250 to establish a lectureship on cancer and bring noted scientific speakers to the quadrangles.

INDIANA

State Medical Meeting at Indianapolis.—The eighty-ninth annual session of the Indiana State Medical Association will be held at the Murat Temple, Indianapolis, October 4-6. Out of state speakers will include:

Dr. Henry F. Helmholz, Rochester, Minn., Recent Advances in Pediatrics as Applied to General Practice.
Dr. Charles A. Elliott, Chicago, Management of Pneumonia.
Dr. Henry S. Ruth, Merion Station, Pa., Physical Signs of Inhalation Anesthesia.
Dr. Walter E. Dandy, Baltimore, Mènière's Disease.
Dr. Frank E. Adair, New York, Tumors of the Breast.
Dr. Everett D. Plass, Iowa City, Obstetrics for the General Practitioner.
Dr. Herman L. Kretschmer, Chicago, Cystitis in Women and Female Children.

Among the Indiana physicians on the program are the following:

Dr. Edwin Rogers Smith, Indianapolis, Metrazol in the Treatment of Schizophrenia.
Dr. Wayne R. Glock, Fort Wayne, Treatment of Hip Fractures.
Dr. Frank W. Ratcliff, Lafayette, Nupercaine Combinations Used in Spinal Anesthesia—Eight Year Review.
Dr. Charles N. Combs, Terre Haute, Cyclopropane—A Résumé of Personal Experience.

A symposium on syphilis will be held Wednesday afternoon with the following speakers: Drs. Wemple Dodds, Crawfordsville; Minor W. Miller, Evansville; Floyd R. Nicholas Carter, South Bend, and Clifford L. Williams, Logansport. Dr. Herman M. Baker, Evansville, will preside at the annual banquet Wednesday evening when the certificate of merit will be presented posthumously to Dr. Edmund D. Clark, Indianapolis, president in 1937 of the state medical association. Wisconsin speakers will be Drs. Rock Sleyster, Wauwatosa, Wis., President-Elect, American Medical Association, whose subject is not announced, and George E. Vincent, LL.D., Greenwich, Conn., on "The Pain of Thinking."

KENTUCKY

Personal.—Dr. Otis R. Lynch, Brandenburg, has resigned as health officer of Meade County to enter private practice in Marengo, Ind. — Dr. Ollie M. Goodloe, Maysville, has resigned as health officer of Mason County to become field director of the state board of health for Eastern Kentucky, with headquarters in Lexington. Dr. Chadwick W. Christine, Louisville, has been appointed to succeed Dr. Goodloe.

Society News.—Dr. J. Watts Stovall, Grayson, addressed the Carter County Medical Society, Olive Hill, recently on "Care of the Indigent Sick and Responsibility of the Government for the Payment for This Care."—The Rockcastle County Medical Society was recently reorganized with Dr. Nevil M. Garrett, Brodhead, as president; Dr. Thomas A. Griffith, Mount Vernon, vice president, and Dr. Lee Chesnut, Mount Vernon, secretary. Dr. Eugene J. Brown, Stanford, addressed the June meeting on diagnosis.

MAINE

Dr. Bragdon Honored at State Fair.—Dr. Fred A. Bragdon, Springvale, was honored August 25 when a day at the state fair in Acton was dedicated to him in appreciation of his services to the community. A veteran race horse owner, he was presented with a gold horse mounted on a marble slab and a check with which to purchase a "horse of your own selection," newspapers reported. Mrs. Bragdon received flowers. Following his graduation from Bowdoin Medical School, Brunswick-Portland, in 1883, Dr. Bragdon practiced in Shapleigh for about nine years, then moved to Lynn, Mass., for one year. Then he moved to Springvale, where he has practiced ever since. He was presented with the fifty year medal by the Maine Medical Association five years ago. He will be 80 years old in October. Gov. Lewis O. Barrows was among the speakers at the ceremony.

MICHIGAN

Study Program.—The Flint department of health sponsored a study program at Mott Camp, Flint, September 6-10. The first three days were devoted to discussions of public health activities, the last two to a study by nurses of the health department's technic and procedure. The entire personnel of the department, including physicians, nurses, sanitarians, health educators, laboratory technicians and clerks, stayed at the camp the first three days, while only the nurses remained for the last two. The speakers included Drs. Don W. Gudakunst, Lansing, state health officer; Henry Cook, president of the state medical society, and Bernard W. Carey, Detroit, medical director of the Children's Fund of Michigan.

Upper Peninsula Meeting.—The Upper Peninsula Medical Society held its annual meeting at Sault Ste. Marie August 18-19. Hon. Paul Adams, mayor, gave the address of welcome and speakers on the scientific program included:

Dr. Walter G. Maddock, Ann Arbor, Peripheral Vascular Diseases with Special Reference to Varicose Ulcers and Varicose Veins.
Dr. Carl E. Badgley, Ann Arbor, Back Pain.
Dr. Floyd H. Lashmet, Petoskey, Nephritis and Pyelonephritis.
Dr. William W. Bauer, Director, Bureau of Health Education, American Medical Association, Chicago, Relationship of County Health Units to the Profession.

Dr. James D. Bruce, Ann Arbor, director of postgraduate medical education, University of Michigan, Ann Arbor, addressed the banquet in the evening on "A Doctor's Inventory." Officers elected at the meeting included Drs. Albert H. Miller, Gladstone, president, and Stephen Mason, Menominee, vice president. The secretary will be chosen by the Escanaba group, which will act as host to the society next year.

MINNESOTA

Alumni Reunion.—The University of Minnesota Medical Alumni Association will hold its annual business meeting at a luncheon at the University Hospitals October 14, the day preceding the homecoming game with Michigan. Dr. Harold G. Benjamin, Minneapolis, has been appointed chairman of the program committee for the clinical presentation at the hospitals Friday morning.

"Miracle Man" Forfeits Bond in Minnesota.—The bail bond of J. A. White, alias Professor White, alias Dr. White, was ordered forfeited by Judge F. A. Alexander of the municipal court at Owatonna, and a bench warrant was issued for his arrest August 3, following his failure to appear in court for a preliminary hearing after his arrest for practicing healing without a basic science certificate. The order means that the bondsmen will have to pay Steele County \$750. White was arrested July 24 at Ladysmith, Wis., following a joint investigation of his activities by the Minnesota State Board of Medical Examiners and Steele County. He waived extradition and was returned to Owatonna, where he was released on bond. White arrived in Steele County in the latter part of March driving a Packard car with Georgia license plates, according to the state board of medical examiners. Because of a bad snowstorm, he asked for shelter at the home of farmers a few miles west of Owatonna. He rep-

resented himself as "Professor" White and also as "Dr." White; he claimed to be a psychoanalyst and in a few days was diagnosing ailments and suggesting pills, tablets and capsules, charging each patient from \$6 to \$40. The medicine was purchased by White at drugstores in Owatonna for a fraction of the amount he charged. When White's fingerprints were sent to the federal bureau of investigation at Washington, Sheriff E. T. Helgeson of Steele County was notified that White was wanted at Jesup, Ga., for swindling and practicing medicine without a license. White in the meantime had secured his release at Owatonna on bond and started for parts unknown. He also had been arrested in Detroit in 1918 on a charge of "larceny by trick." He claims to have been born in 1858 but appears to be between 60 and 65 years of age; he is accompanied by Mrs. White. Newspapers reported in 1922 that the "miracle man," "Prof." J. A. White, was ordered to leave Shelbyville, Ind.

MISSISSIPPI

Society News.—At a meeting of the Coast Counties Medical Society in Biloxi July 6, Dr. Frank O. Schmidt, Ocean Springs, discussed "Volvulus of the Cecum."—The North Mississippi Medical Society was addressed in New Albany July 20 by Drs. Joseph E. Green, Laurel, on "Vital Problems Concerning the Mississippi Medical Association"; James P. Wall, Jackson, "Louis Pasteur, the Father of Modern Medicine," and Seale Harris, Birmingham, Ala., "The Relation of the Endocrine Glands to Hyperinsulinism."—The Hattiesburg Clinical Society was organized recently with Drs. Theophilus E. Ross Jr. as president; Richard H. Clark, vice president, and Lawrence B. Hudson Jr., secretary, all of Hattiesburg.

NEW JERSEY

President of the State Medical Society.—Dr. Stuart Zeh Hawkes, Newark, writes that his father, Dr. Edward M. Zeh Hawkes, Newark, was named president-elect of the Medical Society of New Jersey at the annual meeting in May. A news item in THE JOURNAL August 6 gave the son's name as the officer elected.

State Society Sponsors Clinical Conference.—The Medical Society of New Jersey will sponsor a clinical conference October 6-7 in the various hospitals of Newark and Essex County. Dr. Harrison S. Martland, chief medical examiner of the county, will conduct a clinicopathologic conference at the Academy of Medicine, Newark, in the afternoon of the first day. Sessions Friday will be held in seventeen hospitals and medical centers by 179 members of the staffs.

NEW YORK

Typhoid Closes Children's Camp.—Three cases of typhoid recently appeared in a camp for children operated by the Heckscher Foundation for Children of New York at Putnam Valley in Putnam County near Peekskill. On the advice of the state department of health, about 650 children who had been in the camp since July 1 were returned to their homes. Investigation gave evidence that the source of the disease was in a polluted brook from which the water supply was pumped. The water was chlorinated and passed through filters, but it is believed that the chlorine demand rose greatly following heavy rains in July and permitted incompletely chlorinated water to enter the supply, according to a report in *Health News*.

New York City

Report on Blood Banks.—About 2,000 persons have donated blood for "blood banks" established in the city hospitals in June, the commissioner of hospitals recently reported. There have been more than 600 in Brooklyn alone. The banks were begun this year when it became apparent that funds for hiring professional donors would be exhausted before the year was over. In 1937 the city expended \$171,599.86 for this purpose.

Automobile Deaths Reduced.—Automobile accidents caused 414 deaths in the first six months of 1938 in New York City, nineteen less than the number in 1937. The number of injured also decreased from 15,317 to 14,334. Fifty-five children were killed, compared with sixty-nine in the first six months of last year. Carelessness in crossing against traffic lights caused the deaths of 109 and jaywalking caused seventy deaths. Collisions between vehicles caused sixty-three deaths and injuries to 5,357. Other causes were: running off sidewalk into roadway, twenty-six deaths; reckless driving, twelve; skidding, twelve; falling from moving vehicles, seven, and vehicles turning corners, eight. Under the cause "driver of vehicle intoxicated" there were two deaths and sixty-six were injured.

NORTH CAROLINA

Venereal Disease Clinic at Charlotte.—The city of Charlotte and Mecklenburg County, in cooperation with the state board of health, has established a venereal disease clinic, with Dr. Paul J. Chambers, Charlotte, as director. Dr. Leon A. Beardsley, Waverley, health officer of Humphreys County (Tenn.), will be in charge temporarily while Dr. Chambers takes a special course in syphilis control at Johns Hopkins University School of Medicine, Baltimore.

PENNSYLVANIA

District Meeting.—The annual meeting of the Ninth Councilor District of the Medical Society of the State of Pennsylvania was held in Punxsutawney September 8. Speakers at the morning session were Drs. Benjamin F. Coc, Indiana, and Joseph C. Lee, Clymer, on "Backache"; Thomas Craig McKee, Kittanning, "Gynecologic Treatment in General Practice"; Joseph M. Lukehart, Punxsutawney, "Acute Head Colds, Complications and Treatment." At the afternoon session Dr. William J. Armstrong, Butler, discussed the American Medical Association's survey of medical needs; Dr. Chauncey L. Palmer, Pittsburgh, "What We May Expect in Medical Legislation," and Dr. Elmer Hess, Erie, "The Physician in Self Defense: How Shall He Defend Himself?"

TENNESSEE

Physician's Library Goes to Hospital.—The medical library of the late Dr. Victor D. Holloway, Knoxville, has been presented to the Knoxville General Hospital by his widow and daughter. The library, containing 525 volumes and 137 issues of medical journals, has been placed in a special alcove adjoining the hospital record room. Dr. Holloway died June 24.

Society News.—Dr. William D. Haggard, Nashville, among others, addressed the Hardin, Lawrence, Lewis, Perry and Wayne Counties Medical Society in Clifton July 26 on "Diagnosis of Surgical Diseases of the Rectum with Special Reference to Cancer." The society met June 28 at Shiloh National Park with physicians from several other counties in Tennessee and Mississippi as guests. The speakers were Drs. John B. Nuckolls, Jackson, "Urinary Tract Infections"; Stanley A. Hill, Corinth, Miss., "Fractures of the Elbow"; Le Roy B. Brackstone, Iuka, Miss., "Amoebiasis," and John L. McGehee, Memphis, "Cryptorchidism and the Torek Operation for Relief."—Drs. Carl W. Brabson, Telford, and John L. Hankins, Johnson City, addressed the Washington County Medical Society July 7 on "Hypertrophy of the Prostate" and "Backache" respectively.

WEST VIRGINIA

Campaign to Encourage Birth Registration.—The West Virginia State Health Department with the cooperation of the U. S. Bureau of the Census will sponsor a "Birth Registration Week" during the week of October 2. A central committee representing the health department, the census bureau, the state medical association, the parent-teacher association, the state federation of women's clubs, the state agricultural extension division, the state public assistance department, the American Legion and the WPA has planned an intensive campaign for each county, designed to make every citizen aware of the importance of birth registration.

Enlarge Hospital for Crippled Children.—A new seventy-five bed wing of the Morris Memorial Hospital for crippled children near Milton was opened July 10. The unit cost \$250,000, made available from WPA funds. In 1935 the state legislature appropriated \$20,000 for improvements and in 1937 \$64,000 to assist the hospital to take advantage of federal aid. When the project is completed there will be a main hospital building with two wings of seventy-five beds each, a central administration building with operating rooms, offices, nurses' and surgeons' quarters, a hydrotherapeutic unit, a school building and various farm buildings. In addition to one wing of the hospital, the hydrotherapeutic building, the dairy barn, a road to the main highway and several small farm buildings have been completed.

WYOMING

Plague Infection.—According to *Public Health Reports*, plague infection was demonstrated in a pool of eighteen fleas collected from eight prairie dogs (*Cynomys leucurus*) shot June 27 eight miles northwest of Evanston, Uinta County, and in animal tissue and in pools of fleas from *Citellus armatus*, all within from two to eight miles of Cokeville, Lincoln County.

CANAL ZONE

Society News.—The Medical Association of the Isthmian Canal Zone met at the Gorgas Memorial Laboratory, Panama, Republic of Panama, June 21, with the following speakers: Drs. Jesse C. Ellington, Ancon, on "Infant Mortality in Panama City"; Maximo Carrizo y Villarreal, Panama, "A Preliminary Report on the Roentgenologic Aspect of Childhood Tuberculosis in Panama City"; Agustín A. Sosa, Panama, "Pulmonary Tuberculosis in the Adult as Seen in Panama" and Amadeo Vicente-Mastellari, Panama, "Diphtheria Studies in Panama."

GENERAL

Journal of Social Ophthalmology.—The International Association for the Prevention of Blindness has begun publication of the *Journal of Social Ophthalmology*, a quarterly with articles in both French and English. Its purpose, according to an announcement from the National Society for the Prevention of Blindness, is to facilitate the exchange of information throughout the world in the organized campaign for the prevention of blindness and the conservation of vision. The international association's headquarters are at 66 Boulevard Michel, Paris.

Society News.—Dr. McIver Woody, New York, was named president of the American Association of Industrial Physicians and Surgeons at the recent annual meeting in Chicago. Dr. Clarence D. Selby, Detroit, became president and vice presidents elected were Drs. Daniel L. Lynch, Boston, and Lloyd Noland, Fairfield and Birmingham, Ala. Dr. Volney S. Cheney, Chicago, was reelected secretary.—The annual meeting of the Polish Medical and Dental Association of America was held in Pittsburgh August 25-27. Among the speakers were Drs. Lester Hollander, Pittsburgh, on "Skin Disease from the Standpoint of the General Practitioner"; Ralph E. Tafel, Pittsburgh, "Human Sterility"; Francis L. Zaborowski, Philadelphia, "Important Factors in Speeding Up Postoperative Wound Healing," and Samuel Glenn Major, Pittsburgh, "Mouth and Face Surgery."—The National Recreation Association will hold its annual meeting in Pittsburgh October 3-7.

Changes in Status of Licensure.—The State Medical Board of the Arkansas Medical Society announces the following:

Dr. Luther W. Copeland, Trumann, license restored June 9.

The Massachusetts Board of Registration in Medicine announces the following:

Dr. Russell B. Street, Conway, license restored April 28.

The Minnesota State Board of Medical Examiners reports the following action:

Dr. George H. Espenlaub, Evansville, Ind., license revoked May 13 on his conviction for assault and battery.

The New York state board of medical examiners recently reported the following action:

Dr. Julius Warren Blakely, whose last known address was Highland, N. Y., license revoked April 14, on his conviction of a felony.

Dr. Herman B. Elster, whose last known address was 505 West End Avenue, New York, license suspended for nine months.

Patients at National Leprosarium Plead for New Location.—At a mass meeting August 17 the patients at the National Leprosarium, Carville, La., adopted a resolution requesting a change in location for the national leprosarium and asserting their belief that the present location is detrimental to their health and well being. Reviewing the history of the leprosarium, the resolution states that Carville was originally the site of the Louisiana State Leprosarium, established in 1894. This site was accepted as a last resort when favorable locations in other communities could not be secured, because of the objections of residents. Thus, it is stated, the unsuitability of the Carville location was recognized then and a five year lease of the place was made as a temporary measure. For eight years no improvements were made and in the meantime another site was purchased. Plans to move the leprosarium to the new location were frustrated when residents of the vicinity burned the buildings. The present site at Carville was purchased as a permanent location in 1905. The U. S. government purchased the Louisiana leprosarium in 1921. A national committee spent four years investigating other locations and recommended sites in several other states as preferable to Louisiana, but the objections in these states resulted in the purchase of the Louisiana site. Emphasizing the fact that malaria is prevalent in the tropics, the resolution points out that from May 1, 1935, to May 1, 1936, there were 155 cases of malaria among the patients at the leprosarium, 42 per cent of the entire patient body. A similar percentage

of the personnel was also affected. Of the 155 patients forty-two died before May 1, 1938; of the deaths it was said that malaria was a contributing cause or at least an accelerating factor. Other patients in this group, with their resistance weakened by malaria, have experienced marked retrogression of their clinical condition and cases that had been in a quiescent state for twelve years or more have been reactivated, it is alleged. According to the resolution, the present location is undesirable not only from a climatic standpoint but from a geographic one as well, the hospital being situated in the inner bend of the Mississippi River, which bounds it on three sides, and the peninsular area thus formed is a swampy lowland with elevation below that of the normal river stage, and the yearly flood waters are a constant menace to life and property. The resolution also points out that in forty-four years of the leprosarium's existence both as a state and as a national institution no member of the medical and nursing staff or of the 200 employees has been known to contract the disease as a result of contact with the patients or otherwise, and that no case of leprosy has developed in the adjoining community. Submitted on behalf of the Patients' Federation, representing the patient body of the institution, the resolution concludes with an appeal to the U. S. Public Health Service to exert its utmost efforts toward securing a suitable location for the construction of a national leprosarium; a site which, as far as possible, shall have a climate with none of the objectionable features mentioned and which shall promote rather than retard recovery as well as the return of the patients to society as no longer a menace to others. Congress recently appropriated \$5,000,000 for the construction of new buildings at the leprosarium.

American Roentgen Ray Society.—The thirty-ninth annual meeting of the American Roentgen Ray Society will be held at Haddon Hall, Atlantic City, N. J., September 20-23. There will be a symposium on heart disease in which the following will participate: Drs. Fred J. Hodges, Ann Arbor, Mich.; George P. Robb and Israel Steinberg, New York; Eugene Freedman, Cleveland; Merrill C. Sosman and George Levene, Boston; Hugo Roesler, Philadelphia, and Marcy L. Sussman, New York. In a symposium on growth the speakers will be Drs. Stanley P. Reimann and Baldwin H. E. W. Lucke, Philadelphia; Phineas W. Whiting, Ph.D., Jacob R. Schramm, Ph.D., and Frederick S. Hammett, Ph.D., Philadelphia. Among the speakers will be the following:

Drs. Karl Kornblum and Lawrence C. Fisher, Philadelphia, Carcinoma as a Complication of Achalasia of the Esophagus.
Dr. Jacob Gershon-Cohen, Dr. Harry Shay and Samuel S. Fels, Philadelphia, The Relation of Meal Temperature to Gastric Motility and Secretion.
Drs. William Snow and Meyer Rosensohn, New York, Roentgen Visualization of the Soft Tissues in Pregnancy.
Drs. Whitmer B. Fitor and Charles A. Waters, Baltimore, The Present Status of Roentgen Treatment of Sinus Infections.
Dr. Lawrence Reynolds, Henrietta S. Hayden, Ph.D., and Kenneth Corrigan, Ph.D., Detroit, Roentgen Ray Diffraction Studies of Human Nervous Tissue.
Dr. Carleton B. Peirce, Montreal, Tuberculous Tracheobronchitis.
Lauriston S. Taylor, A.B., and George Singer, A.B., Washington, D. C., The Use of Protection for X-Ray Voltages Up to 400 Kilovolts.
Dr. Sydney J. Hawley, Danville, Pa., A Method for Obtaining Greater Ratio of Deep to Surface Dosage.

This year the society introduces a series of educational courses of one hour each day. Dr. Joseph McFarland, Philadelphia, will deliver the Caldwell Lecture Tuesday evening September 20 on "Keeping in Step with Science." The annual banquet will be Thursday evening. The annual golf tournament will be held Monday September 19 at the Seaview Golf Club; this year for the first time the Willis F. Manges Memorial Cup will be awarded.

CANADA

Society News.—Dr. John H. L. Simpson, Springhill, was elected president of the Medical Society of Nova Scotia, now the Canadian Medical Association, Nova Scotia Division, at the annual meeting in Halifax in June. Vice presidents are Drs. Henry K. MacDonald, Halifax, and Alexander B. Campbell, Bear River, and the secretary is Dr. Harry G. Grant, Halifax. The next annual meeting will be at Digby.

Otolaryngologist Wins British Award.—Dr. William J. McNally, otolaryngologist to the Royal Victoria Hospital, Montreal, was recently awarded the Dalby Prize of the Royal Society of Medicine of England "for the best work in otology published or done during the previous five years." The prize, which is a check for 100 guineas, was established fifteen years ago by Lady Dalby as a memorial to Sir William Dalby. Previous recipients of the prize were Drs. Otto Mayer of Austria and Albert A. Gray of Scotland. Dr. McNally has been conducting research on the functioning of the internal ear.

FOREIGN

Society News.—Dr. Thomas Fraser, consulting physician of the Royal Infirmary, Aberdeen, Scotland, was chosen president of the British Medical Association for 1939-1940. Dr. Colin D. Lindsay, Plymouth, is the president for the current year.—At a meeting of the Osler Club of London July 12 on the eighty-ninth anniversary of the death of Sir William Osler, Dr. Thomas Archibald Malloch, New York, librarian of the New York Academy of Medicine, delivered the eleventh Oslerian Oration on the life and work of Osler. Dr. Harvey Cushing, Sterling professor of neurology, emeritus, Yale University School of Medicine, New Haven, also spoke.

Personal.—Charles R. Harington, Ph.D., professor of pathologic chemistry, and Dr. William W. C. Topley, professor of bacteriology and immunology, in the University of London, have been appointed members of the Medical Research Council to succeed Dr. Alfred J. Clark and Sir John C. G. Ledingham, who retire September 30.—William H. Tytler, research bacteriologist of the Welsh National Memorial Association, has been appointed to the David Davis Chair of Tuberculosis in the Welsh National School of Medicine of the University of Wales to succeed Prof. Stevenson Lyle Cummins, who has retired.—Dr. Carl G. Jung, professor of psychology at the University of Zurich, Switzerland, received the honorary degree of doctor of science from Oxford University, where he presided at the tenth International Congress of Medical Psychotherapy.

Cholera Vaccine for China.—The Chinese government has recently appealed to the League of Nations for six million doses of cholera vaccine to combat the epidemic in the central and southwestern regions. The *Lancet* reports that the following countries have responded: Australia and Ceylon 500,000 doses each, Philippine Islands (Red Cross) 1,000,000, Denmark 130,000, Rumania 1,000,000, Yugoslavia 500,000, Turkey 1,000,000 and Egypt 180,000. The Pasteur Institute at Hanoi had previously sent 250,000, according to this report; the National Institute of Bacteriology, Buenos Aires, has offered 200,000, and the American Red Cross was preparing to ship 3,000,000. The League's epidemic commission has established three units, which have undertaken smallpox vaccination on a large scale and measures against typhus, including inoculation, delousing, supervision of refugees and establishment of hospitals. Two tons of quinine has been sent to China for the campaign against malaria and efforts are in progress to reduce syphilis, rabies, plague and the diseases of malnutrition.

Deaths in Other Countries

Sir David P. D. Wilkie, professor of surgery, University of Edinburgh; surgeon to the Royal Infirmary, Edinburgh; member of the Medical Research Council; died in London August 29, aged 56.

Government Services

Examination for Army Medical Corps

The War Department announces an examination December 5-9, both dates inclusive, for the purpose of qualifying candidates for appointment as first lieutenants in the Medical Corps, Regular Army, to fill vacancies occurring during the fiscal year 1939. The examination is open to all male graduates of acceptable medical schools who have completed a year's internship in an approved hospital and who will be not more than 32 years old at the time it is possible to tender a commission. The examination will be conducted by boards of officers in various parts of the United States and will consist of a physical examination, a written examination in professional subjects and a determination of the candidate's adaptability for military service. Licentiates of the National Board of Medical Examiners may be exempted from the written professional examination. Information and application blanks may be obtained from the Adjutant General, War Department, Washington, D. C. Applications will not be considered after November 19.

CORRECTION

Percentage of Necropsies.—In the Educational Number of THE JOURNAL, August 27, the percentage of necropsies for the Research Hospital, Kansas City, Mo., was incorrectly listed as 19 instead of 69 per cent.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Aug. 20, 1938.

The Annual Meeting of the British Association

The annual meeting of the British Association for the Advancement of Science was held at Cambridge. As usual, some of the papers had a special interest for physicians.

VISION AIDED BY SCIENCE

The president, Lord Rayleigh, took natural vision and vision aided by science as the subject of his address. He said that the combination of qualities of the human eye which allowed rapid changes to be followed was ideal for nature's primary purpose, finding subsistence under primitive conditions and fighting the battle of life against natural enemies. The use of lenses was one of the greatest scientific advances, but we did not know who made it. Spectacle lenses were a medical invention dating from about A. D. 1280. Lenses led to the telescope and the microscope. In theory there was no limit to the telescope, but there was a definite limit to the microscope, depending on the structure of light. Something, but not very much, could be gained by the use of ultraviolet radiation instead of visible light, and it then became necessary to work by photography. But here we had not come to an end and had two alternatives. Paradoxical as it might seem, we could make out of empty space lenses for certain radiations, or we could make optical observations without any lenses at all. Cathode rays could be bent by electric or magnetic forces, and a system of "electron optics" had been elaborated. A beam of cathode rays issuing from a point could be reassembled into an image, and a magnified image of the sources of electrons could be formed on a fluorescent screen. After a reference to the "electron microscope," he said that obscure regions between the smallest organisms and the largest crystalline structure might be explored with the electron microscope. Color vision was one of nature's most wonderful achievements, which anatomy did not explain. The retinal cones were probably responsible for it, but no division into three kinds corresponding to the three color sensations had ever been observed. Nor did any known anatomic peculiarity distinguish a color-blind from a normal eye.

THE PERVERSION OF ANTHROPOLOGY

In the Section of Geography Griffith Taylor, professor of geography in the University of Toronto, said that today the social sciences were challenged by the forces of reaction, the perverted use of anthropology and sociology to advance the views of some of the totalitarian nations. Geographers might do yeoman service by the scientific teaching of what was becoming known as cultural geography. Referring to his twenty years of work on the migration tone theory of racial evolution, Professor Taylor said that all the progressive nations were built up of the same three stocks, Alpine, Nordic and Mediterranean. When this thesis was accepted much of the evil structure based on race prejudice must fall. Race prejudice was but another name for ethnologic ignorance. We were all agreed that the term Aryan could be applied only to speech, but few people realized that the term Jew could be used only in connection with religion. We needed a new term to express a group linked by purely cultural characters, such as language or religion. For instance, in Canada we did not have a French race, since Frenchmen might belong to any of the three distinct races. We had only a French cult linked closely by religion and to a less extent by language. So also we should learn to speak of a Jewish cult, since this large group was linked closely by religion and to a lesser degree

by language. The Jews, like the Germans, were of two different races. If they came from Poland they belonged to the Alpine race; if from Spain, to the Mediterranean. The linguistic divisions in Europe were Aryan and Altaic, but the race divisions were Nordic, Alpine and Mediterranean. The German nation was half Nordic and half Alpine. The Jews in Europe belonged to a cult, and racially about three fourths were broad-headed Alpines, like the other mid-Europeans. The explanation was the widespread conversions to Judaism which took place in the past in eastern Europe. Racially the Jews were Alpines like the rest of the South Germans.

The Health of the Nation

A steady improvement in the national health is shown in the nineteenth annual report of the ministry of health, which has just been published. A comparison with 100 years ago reveals the magnitude of the advance. In 1838 the general death rate was 22.4 per thousand compared with 12 today. The death rate for tuberculosis was 4,480 per million, against 700 today. More than 1,000 persons per million died from smallpox and twenty-two from cholera, while there was not a single death from these diseases last year. The death rate for typhoid was 1,228 per million, against 5 today. The maternal mortality, which has been unsatisfactory and refractory, shows a substantial fall. The rate in 1937 was 3.1 per thousand births, against 3.6 in 1936 and 3.9 in 1935. The infant mortality was 58 per thousand births, compared with 59 in the previous year, but was slightly above the record figure of 57 in 1935. There are now 3,145 infant welfare centers in England, an increase of ninety-four over 1936. The crude death rate from tuberculosis per million in England and Wales was 695, against 692 in 1936 and 718 in 1935. There was a decrease in the reported cases of enteric fever (including paratyphoid) from 2,490 in 1936 to 2,149 in 1937. A feature of the report is the presentation of the statistics for Wales in a separate table. They show the great fall in the birth rate which has gone on in Great Britain for many years. In 1901, when the population of Wales was just over 2,000,000, there were 62,233 births; in 1937 the population was nearly 2,500,000 but there were only 37,175 births, a fall of over 50 per cent. During the same period the death rate fell from 18.1 to 10.5 per thousand but the infant mortality fell from 161 to 63 per thousand live births, which to some extent counteracted the effect of the fall of the birth rate. Another gratifying feature was a fall in the maternal mortality from 6.61 per thousand births in 1904 to 4.54 in 1937, the lowest yet attained.

The Agreement Between the Various Schools of Psychotherapy

At the tenth International Congress for Psychotherapy, which was held at Oxford, Prof. C. J. Jung, the president, gave an address in which he explained fourteen points on which agreement had been reached between the conflicting schools by the Swiss branch of the congress. Because of want of agreement it had proved impossible to include psychotherapy in an academic curriculum, but there was more common ground than was generally realized. The points of agreement were as follows: The first objective was diagnosis, which depended on the anamnesis—the relation of the patient to his difficulties and the symptoms. The results showed that there were forms of illness which had nothing to do with bodily disturbances but were intelligible only in terms of the mind. The method of diagnosis was therefore focused not on the seat of illness but on the general psychic disposition. It considered all possible means of expression: premeditated speech, free association, fantasies, dreams, symptoms and demeanor. It found an etiology reaching down into the depths of the personality and so transcending the limits of the conscious mind. The dark por-

tion of the psyche was called the unconscious. This investigation led to the discovery of unconscious fixation on crucial situations and persons significant in the patient's childhood. These fixations had both a causal and a purposive aspect and set tasks for future fulfilment. One of the tasks of psychotherapy was to illuminate the factors out of which the illness developed, and its method was the analysis and interpretation of all forms of expression. The therapeutic development of the patient depended on the relation between him and the physician, and this formed the basis of his relation to society. In treatment this relation took the specific form of transference, which was the projection of unconscious contents and appeared as a transference neurosis. The reduction of the transference neurosis showed it to have been laid down in the unconscious fixations of childhood. Behind these individual fixations, collective unconscious factors were assumed. The new contents had to be realized as parts of the personality, because only in this way could the patient feel his responsibility toward them.

At the close of the congress Professor Jung answered a number of questions. Psychology, he said, was such a large and difficult subject that the psychotherapist could not rest on his own training alone but must borrow from philosophy, anthropology, history and literature. Primitive psychology solved many difficulties. Primitive peoples had few traces of what we call "volition." For doing anything unusual they had to work themselves up ceremonially. At about the age of 36 the personality expanded into life, like an exploding celestial body. After 40 depression was frequent among those who had not fulfilled their ambitions. The great religions were preparation for the second half of life. Religious experience was a worldwide and universal phenomenon. One who did not know what it is was not normal. He did not recognize his own religious experience, and some other parts of life were exaggerated by the energy which should have gone into that experience. It was an insanity of the white man that he had lost the religious order of life.

The Relation of Pulmonary Tuberculosis to Poor Housing

A book entitled "Tuberculosis and Social Medicine," by Dr. Etienne Bernard, has just been published. In the chapter on proper housing conditions in relation to tuberculosis, the author states that wherever attention has been given to sanitary living conditions as a governmental policy the death rate for tuberculosis has greatly decreased. This is especially true of Great Britain, but thus far little has been done in this direction in France. A study made in 1919 of all houses in which at least ten deaths from tuberculosis had taken place from 1894 to the end of 1918 revealed a total of 4,750 such houses, located chiefly in two densely populated wards of Paris. It was found that 186,000 persons lived under most inadequate and unhealthy conditions. It was then decided to demolish such houses and construct 20,000 others, to which the tenants would be moved. This plan has been carried out so far as the buildings themselves are concerned, but not more than 3 per cent, or 5,500, of the persons who were lodged in hovels and similar insanitary homes were able to move to the new buildings; the others could not afford to pay the rent asked by the city of Paris. In order to meet this objection, the city council has recently voted to construct 5,000 new houses or flats, to be rented at a low price, but it has been found that on account of the present high cost of construction it is difficult if not impossible to solve the problem in this manner. An effort has been made to build some "garden cities" in the suburbs of Paris to take care of 32,000 persons, and about 200,000 houses

have been constructed in other parts of France. Here again the government is confronted with the inability of those who live in shambles to pay the rents demanded for more sanitary homes. Since 1922 nearly three million houses have been constructed in England, at a cost which is nearly ten times that allotted in France for similar work. In Germany and Italy huge sums are also being spent for better housing conditions. Dr. Bernard in closing his chapter emphasizes the desirability of impressing the French government with the necessity of more liberal appropriations for this work.

Neurologic Complications of Therapeutic Pneumothorax

Reference was made in a previous letter to a paper by Dr. Weissmann-Netter in which he reported three cases in which transitory symptoms referable to the central nervous system had followed insufflation of air in the treatment of pulmonary tuberculosis. The discussion of the subject was continued at the June 10 and June 17 meetings of the Société médicale des hôpitaux. The first paper was by Drs. Etienne Bernard and Boris Kreis, who were of the same opinion as Dr. Weissmann-Netter, that these complications are rare. The patient, a woman aged 33, had pulmonary tuberculosis of eight years' duration. She was seen by the authors for the first time in March 1938. No sequels were observed after three insufflations, but as soon as 75 cc. of air had entered the pleural cavity the pressure was suddenly raised in the insufflation apparatus. This was immediately followed by a few spasmodic movements of the right side of the face and the right arm, as well as by hemiplegia on the left side, which were believed to be due to an air embolism. Ability to move the left arm returned in less than a half hour, and only a slight muscular weakness on the left side could be found a few hours later. The chief object of the paper was to call attention to the fact that neurologic complications occur when the insufflation is made in spite of the fact that manometric oscillations are slight or have ceased and the needle on being withdrawn contains blood. These signs show that the lung has been punctured. Air embolism is found also when extensive pleural adhesions exist, so that the air enters only a small pocket and when the pressure exerted in the effort to introduce more air causes the latter to enter some vessel during the breaking down of adhesions. Air embolism can easily occur under either of these avoidable conditions. In the discussion Dr. Sèze added two cases of hemiplegia; the condition followed simple exploratory puncture in one and a therapeutic pneumothorax in the other. In both the lung had been punctured. He advised the use of as small a caliber needle as possible.

Interesting Decision on Medical Responsibility

Since time immemorial it has been the custom for physicians to give their services gratuitously to colleagues and dependent members of their families. The question as to whether the same legal responsibility exists in such cases as when the physician is remunerated for his services is seldom raised. A recent decision rendered by the supreme court here on an appeal from a lower court is of considerable interest. After a series of radiation treatments for which no charge had been made by a radiotherapist, the patient, a physician, had as a sequel severe radiodermatitis. Suit was brought by the physician against the radiotherapist in the circuit court of Besançon in eastern France. The decision in this lower court was to the effect that, although it recognized the duty of every physician to give medical care without compensation to a colleague or to the dependent members of his family, nevertheless the attending physician retains the same responsibility toward the patient as though he had been remunerated for his services.

The supreme court, in reviewing the case on an appeal from this decision of the lower court, reiterated the responsibility, from a legal point of view, of a physician in treating a colleague gratuitously and confirmed the decision of the lower court awarding damages to the physician-patient.

Celebration of Fiftieth Anniversary of Institut Pasteur

The opening session of the first international congress of French-speaking microbiologists, to be held October 26-29, will be devoted to a celebration of the fiftieth anniversary of the Institut Pasteur of Paris. Addresses will be made by Mr. Lebrun, president of the French republic, and Mr. Rucart, minister of public health. The following morning a number of papers will be presented on microbiologic subjects. The October 29 session will be devoted to a discussion of the ultravirus. Information regarding the congress can be obtained by writing to the Association des microbiologistes de langue française, Institut Pasteur, 28 rue du Docteur Roux, Paris 15.

The Campaign Against Psittacosis

Psittacosis has become a domestic disease in Germany. Although the morbidity is still slight in comparison with other infectious diseases, Professor Haagen of the Infectious Diseases Institute, Berlin, emphasizes that all possible preventive measures are necessary to check the increasing frequency of epidemics. The danger of psittacosis should not be underestimated, as the morbidity among domestically bred stocks of psittaceous birds has increased steadily in recent years. The disease has been transmitted to man almost exclusively by the zebra-parrakeet. Among nonpsittaceous birds the canary bears particular watching, since it appears to be extremely susceptible to the virus of psittacosis. In Austria a few years ago canaries were responsible for numerous cases in man. Since the ban on the importation of parrots, which was imposed in 1930, foreign birds have no longer been a conspicuous source of infection.

In the years 1932 and 1933 a recession in human cases of psittacosis was noted, but in 1934 a further increase began. At the same time the presence of the infection in latent form was determined in large numbers of domestically bred parrakeets. A comprehensive antipsittacosis campaign was then initiated. The government declared psittacosis to be a menace to public health and decreed that all deaths, sickness and suspicion of sickness from this disease must be reported. The new law further provides for police supervision of the commercial breeding of parrots and parrakeets. The appearance of sickness in several birds in a store or breeding establishment must be reported to the authorities. If psittacosis is subsequently found, the police may order the destruction of the entire suspected stock. The veterinary board of control is also empowered to confiscate and sequester any suspected stocks. The further sale of the birds can be prohibited, in which event the breeders and dealers are suitably compensated. If psittacosis is established, an attempt is made to trace the infection to its origin by a study of the history of the particular stock for five preceding months at least.

The older legislative measures applied only to commercial dealers and breeders. Experience has meanwhile taught that healthy birds often become infected in small, noncommercial breeding establishments. Accordingly on April 1, 1938, a new law became effective which places all aviculture of this sort under official supervision. All birds of the parrot kind must now be secured with foot-rings. The new legislation envisages control of an important source of infection, the noncommercial

breeding establishments; this is all the more necessary as the private maintenance of parrakeets has assumed extraordinary proportions in Germany. If within a reasonable period psittacosis, which is an avoidable infectious disease, has not been abolished in Germany, a general ban on all psittaceous birds is officially contemplated. Such a ban would mean the disappearance of every source of infection.

The Care of Premature Infants

Before the Berlin Pediatric Society, Dr. Körnig reported that at the Municipal Children's Hospital, Charlottenburg, excellent results in the care of premature infants have been obtained by careful observation, proper regulation of heating, sufficient isolation and a judicious dietary of relatively small quantities of breast milk. Of great importance for the prophylaxis of infection is the housing of the babies in single or double cubicles. Feeding is exclusively by means of the pipet or the bottle. The time from birth until the attainment of normal body weight is regarded as the period of standardization. During this period the precise amount of nutrition is scarcely considered except in connection with ability to ingest and the general condition. Artificial administration of hormones is deemed unphysiologic. Vitamin C is administered at an extremely early date; great emphasis is placed on the timely treatment of rickets. As to anemia, only the severe forms are treated with iron and intramuscular injections of blood. In the years from 1935 to 1938 the mortality among 143 premature infants amounted to 23.43 per cent; minus the number of babies dying within twenty-four hours after admission, 15.6 per cent.

According to Dr. Doxiades, the mortality among premature infants at Kaiserin Auguste Victoria-House was formerly more than 50 per cent. Even now among an annual accession of 200 premature infants the rate is still in the neighborhood of 50 per cent. Recent studies have revealed that from 3 to 6 per cent of all premature infants show themselves debilitated later in life. Other hospitals report similar figures.

Professor Opitz reports a mortality of some 50 per cent among premature infants of his clinic. Many of these babies succumb to pneumonia between the sixth and the eighth week, perhaps because this institution is without individual cubicles.

Of interest are the observations of Professor Bessau, the Berlin ordinarius of pediatrics. At the Children's Hospital of Berlin University a majority of premature infants die within the first twenty-four hours. Extremely careful necropsies have disclosed that fatal pneumonia among premature infants is usually an aspiration pneumonia. The incidence of this disorder can be reduced only by the strictest attention to feeding methods. The use of tiny feeding bottles is recommended. In Professor Bessau's opinion a risk inheres in any deviation from a breast milk regimen, namely any supplementary feeding. Sterilized breast milk is inferior to raw milk, even if the heating has been done with great care.

A New Form of Encephalitis in Germany

Since the epidemics of lethargic encephalitis which took place toward the end of the World War, the public has been disturbed time and again by outbreaks of certain acute inflammatory disorders of the central nervous system. Professor Pette, director of the Hamburg University Neurologic Clinic, has recently published a report on a new type of encephalitic disorder in which the anatomic lesions differ from those observed in any form of encephalitis hitherto observed in Germany. The disorder is characterized by remarkable anatomic changes and a unique clinical syndrome. Three cases, all fatal, were reported. The new form seems nearly identical with encephalitis japonica as well as with the epidemic which erupted in some American cities (St. Louis, Toledo, Kansas City) during 1933. Encephalitis japonica was first thoroughly described by the Japanese authors Kaneko and Aoki in 1928.

New Zealand Practitioners Oppose Health Insurance

In New Zealand, as in Australia, medical practice is at the crossroads. The government is on the point of turning toward socialized medicine by way of compulsory national health insurance for every member of the community. Excellent as this may be for a country with a completely socialized economy, the scope of activity along these lines is strictly limited by financial considerations in any essentially capitalist economy. The New Zealand scheme, despite its enormous cost, provides only a universal general practitioner service.

The great majority of members of the profession are opposed to this scheme on scientific as well as on economic grounds. All are agreed that the promotion of health is a greater object than the treatment of sickness. Without wishing to underestimate the importance of curative medicine, it is felt that national health insurance, which is really a system of indemnification for sickness, does not (in the proposals put forward by the government) materially advance the greater object of the promotion of health. There are conditions in relation to environment, to conditions at work, to domestic help, to nutrition of the young, to preventive medicine and to research which are known to be unsatisfactory. It is felt that attention to these conditions would do far more for the people than the introduction of a costly system of health insurance. Further, the provision of a universal general practitioner service will do nothing toward remedying these deficiencies.

Again, the difficulty of workers in New Zealand is not so much the obtaining of ordinary medical attention in their homes and at consulting rooms as the provision for major illness, home nursing, hospitalization, specialist treatment and laboratory and radiologic investigation. These are the obstacles to complete medical service which the British Medical Association in New Zealand has sought to remove by means suggested in a plan previously submitted to the government, which implied the fixing of an income limit for beneficiaries.

Accurate diagnosis should be the most important function of the general practitioner, who first comes in contact with the patient. Diagnosis is the foundation of medical treatment, and all special diagnostic services should be available for his assistance; otherwise the general practitioner will become divorced from the most essential part of his professional duty. Unfortunately, the average patient is not conscious of the necessity for treatment to be based on accurate diagnosis, as witness the millions spent on "patent medicines." All he asks for is treatment, and under a panel system without auxiliary services treatment is certain to become empirical.

The introduction of a universal scheme abruptly changes the whole character of medical service, and the full consequence of so revolutionary an innovation cannot be foreseen. It involves changes in well rooted habits of the people and methods of the profession as well as the establishment of completely new economic relationship between the profession and the public. Practitioners in New Zealand see in the projected scheme a mistaken approach to the problem of raising the standard of health of the community. Furthermore, it appears to possess no appreciable advantage in the treatment of disease over what obtains at present.

Malnutrition in New Zealand

There is in New Zealand a system of infant feeding which has gained exceptionally wide acceptance. It is more than twenty-five years since the late Sir Truby King introduced this method and it should now be possible to estimate its results in adult life, for by such results the Plunket system must ultimately stand or fall. In view of the League of Nations statement that defects due to improper feeding in early

life are often irreparable, even if followed by a period of proper feeding, the adequacy or otherwise of a system so universally applied becomes exceedingly important.

Dr. E. M. Spencer of Wellington, New Zealand, considers that the Plunket system is responsible for a considerable amount of underfeeding during infancy and thereby paves the way for a state of malnutrition in later years. He points out that, although the system has been in operation for a quarter of a century, the stature and physique of young adults in New Zealand compare unfavorably with those of a generation ago, that the incidence of dental caries in children and adolescents leads the world, and that the annual school statistics are monotonous in the regularity of the figure for malnutrition. During periods of prosperity and depression alike it has remained almost constant at 7 per cent. He has shown that malnutrition exists to an alarming and unsuspected extent in families in which it should least be expected, in homes where money is no object when it comes to providing good food in plenty, sunshine, fresh air and general care. In almost all such cases the children had been under the constant attention of a Plunket nurse. He contends that the most common fault in artificial feeding is the use of too dilute mixtures and that complete digestibility cannot make up for lack of caloric requirements. The use of formulas which are too low in their content of milk solids implies too low a protein intake. Further, he maintains that the weight curves to which New Zealand babies are expected to conform are too low and are in fact lower than those used in New York and London. Moreover, the Plunket system of feeding does not make sufficient allowance for the extra nutritional needs of babies destined to be above the average stature. Lack of adequate food brings poor physical condition and, along with this, lack of appetite. It is doubtful, therefore, whether a child ever makes up the leeway due to insufficient feeding during the first year, and at twelve months he is already a candidate for the group "malnutrition" when he reaches primary school.

Whether it is justifiable to infer that, hand in hand with a remarkable lowering of infantile mortality, the Plunket system is partly responsible for a state of malnutrition among children and young adults is a debatable question. Nevertheless, Dr. Spencer's observations remind us that the problem is not merely to save life during the perilous first year but to adopt those means which shall secure healthy growth and optimal development.

Poliomyelitis in Australia

Since the outbreak of an epidemic of poliomyelitis in Victoria early in June 1937, a total of 2,081 cases has been reported with 106 deaths. This represents an occurrence of eleven cases to 10,000 of population, with a mortality rate of 5.1 per cent. In other states the epidemic has been less severe but with a higher rate of mortality. During the last three months the incidence has fallen almost to nonepidemic prevalence.

In view of the rather unusual character of the epidemic, particularly in the early stages, an isolation of the virus was made in order to establish that the infections were due to the usual type of virus. Burnet and Keogh, working at the Walter and Eliza Hall Institute, Melbourne, have reported that intracerebral inoculation of monkeys with material obtained from the spinal cords of several patients who died produced typical symptoms, with some variability in the incubation period. The virus is more readily transferred to the monkey than strains obtained in nonepidemic periods.

Monkeys that recovered after infection with the recently isolated strain are still partially susceptible to infection with the Rockefeller Institute MV strain, so that, although the virus responsible for the epidemic has significant antigenic resemblance to it, it is not identical with the classic MV strain of poliomyelitis virus.

Surgical Intervention in Appendicitis

Professor Santi recently reported before the Accademia medica "Filippo Pacini" of Pistoia thirty-four cases of acute appendicitis with circumscribed peritonitis on the first or fourth day of the disease. All of the patients recovered after medical treatment. Among fourteen patients who had acute appendicitis with diffuse peritonitis in which medical treatment was administered, five recovered. Among twelve patients suffering from a circumscribed abscess, the latter was spontaneously evacuated and reabsorbed in ten cases. In the early stage of acute appendicitis a prognosis as to the evolution of the disease cannot be made. There are no symptoms by which a plastic type of appendicitis can be differentiated from a perforating appendicitis. It is advisable to follow the old formula of operating whenever possible in the first hours of acute appendicitis. The mortality in these conditions is nil or slight.

Etiology of Gastric Ulcer

Prof. Guido Manni, in a recent lecture before the army physicians in Trieste, discussed gastric and duodenal ulcers. The fact that, among large groups of persons living in the same climate and under the same standards of life, ulcer develops in only a few shows the lack of influence of external factors and the role of some individual factor. The importance of individual predisposition is shown by the frequency of the disease in persons of a lymphatic-chlorotic and anemic constitution. The psychic factor is important. Stefano found emotional conflicts present in thirty cases of gastric or duodenal ulcers which he observed. According to the speaker, the existence of familial gastric disease is of less importance than heredity of vagosympathetic disturbances, which are the predisposing factors for the development of gastric or duodenal ulcers in 25 per cent of the cases. The speaker found syphilis in 3 per cent of his cases. The vascular theory can be partially accepted only in association with the neurogenic one. It is believed that the gastric wall is attacked by the gastric juice only when the circulation of a particular area is disturbed. Generally ulcers occur in areas of the gastric mucosa which are in close contact with the gastric secretion, such as the small curvature and the pylorus. Ulcer frequently develops in patients suffering from hyperchlorhydria and increased peptic power of the gastric secretion, whereas it is rare in persons with normal gastric secretion, and exceptionally rare in hypopepsia. Hyperchlorhydria, although not indispensable for the development of ulcer, exists in 73 per cent of the cases. Disorders of the metabolism of cholesterol have been shown in gastric ulcer. Iarno found hypocholesterolemia in all cases of gastric ulcer. There is also an anaphylactic theory which is supported in Italy by Cesaris-Demel and in the United States by Shapiro and Ivy, who regard the ulcer as an Arthus phenomenon. The insufficiency of vitamins is also a theory. The speaker concluded that the development of gastric ulcer cannot be explained by any of the known theories.

Society Reunion

The Società piemontese of surgery recently met at Turin with Professor Uffreduzzi presiding. Professor Bobbio spoke on sacrococcygeal cordoma. His patient, aged 54, had an operation in 1929 for the removal of a tumor of the sacrococcygeal cavity. Microscopic study of the tumor showed a typical cordoma which recurred in 1933 in a gluteus and in 1938 in the scar on the buttock. The speaker said that sacrococcygeal cordoma is malignant and of a reserved prognosis. The tumor has a tendency to recur in the same place in which it appears at first, and also to produce metastases. The tumor is not sensitive to roentgen irradiations.

Professors Filocchi and Buisson spoke on late results of cholecystostomy. The operation enables the surgeon, by means of introduction of opaque substances, to ascertain whether or not the draining system of the biliary tract is opened. Cholecystostomy was done, from 1932 to 1936, at the surgical clinic of Turin in thirty-six cases. The five patients in the group who had hepatitis died. Of the remaining thirty-one, five died some time after the operation from an intercurrent disease. Thirteen had no more complaints. Recurrence took place in ten patients, six of whom had a second operation.

Articular Fractures in War

A combined session of the Accademia Medica and the Accademia Lancisiana was held at Rome. The participants were prominent surgeons of the capital who are also veterans of various military campaigns. Surgeon General Professor Caccia called attention to the need for better organized treatment of articular fractures incurred in war. The author stressed the numerical importance of injuries of this type. They represent about 25 per cent of all curable war wounds. He then discussed the possibility of cure and proposed that in future the medical corps should be better prepared to treat such injuries both through improved special technicosurgical equipment and a better training of surgeons. At the conclusion of Professor Caccia's address the academies voted the following recommendations: 1. The military authorities should see to it that all military hospital units specializing in the treatment of articular fractures are provided with the most modern equipment and that the surgeons in charge are specially trained in traumatology. 2. All patients with articular fractures, after emergency treatment at the aid stations, should be quickly evacuated to the special hospitals. 3. Sixth year medical students should be required to pass a final examination in a theoretical and practical course in emergency treatment of war wounds, to be given at the premilitary school.

The Therapy of Pneumonia

In the general assembly of the Italian sections on general medicine, which met at Milan to discuss the therapy of pneumonia, it was formally recommended that all health authorities should take an active part in the improvement of present conditions by advocating measures which would facilitate the early diagnosis of pneumonia and hastening the use of specific serotherapy. The national health authorities should find means to assure an ample supply of the required serums.

Marriages

HENRY MURFREE CARNEY, Murray, Ky., to Miss Enid Lee Lindenberg of Nashville, Tenn., at Harbor Springs, Mich., recently.

LEWIS ELLSWORTH HEDGECOCK, Hampton, Iowa, to Miss Pauline Davis of Estherville, July 12, in Novata, Okla.

WILLIAM NORTH DAWSON, Murfreesboro, Tenn., to Miss Mary Frances Monroe of Russellville, Ky., in June.

ROBERT SAMUEL MOSLEY, Miami, Fla., to Miss Elizabeth Stucky of Pahokee, July 10, at Asheville, N. C.

MALCOLM SHIELDS DICKSON, Oakboro, N. C., to Miss Frances Elizabeth Boyette of Ahsokie, July 23.

GEORGE GARDNER DURST, Cincinnati, to Miss Mary Elizabeth Watts of Columbia, S. C., in June.

EVERETT MANSHIP HARRISON, Dunedin, Fla., to Miss Mamie Lou Sharpe in Clearwater, August 8.

HAROLD WRIGHT MUECKE, Macon, Ga., to Miss Marian Hawk of Rimersburg, Pa., June 11.

CLYDE WILSON COLLINGS, New York, to Miss Mary Ann Foley of Portland, Maine, July 21.

ROBERT CLEMENTS to Miss Eunice Tanner, both of Danville, Ill., in Champaign, August 4.

MAURICE JOSEPH COSTELLO to Miss Margaret Therese Moore, both of New York, July 30.

Deaths

John Levy, New York; McGill University Faculty of Medicine, Montreal, Que., Canada, 1926; member of the American Psychiatric Association and the American Orthopsychiatric Association; associate clinical professor of psychiatry at the Columbia University College of Physicians and Surgeons; psychologist to the Canadian National Hygiene Clinic, 1922-1923; clinical assistant to the psychiatric clinic, Royal Victoria Hospital, Montreal, 1925-1926; assistant physician to the Manhattan State Hospital, New York, and clinical assistant, mental hygiene clinic, Bellevue Hospital, 1926-1927; psychiatrist, Institute of Juvenile Research, Chicago, Judge Baker Foundation, Boston, and child guidance clinic, Cleveland, 1927-1928; chief, child guidance clinic, department of psychiatry, Columbia University since 1930; aged 41; died, July 11, in the Beth Israel Hospital, Boston, of chronic interstitial nephritis.

Felix Percy Chillingworth, Boston; Yale University School of Medicine, New Haven, 1907; assistant professor of physiology at the University of Kansas School of Medicine, Lawrence, 1912-1914; assistant professor of physiology and pharmacology at Tulane University of Louisiana School of Medicine, New Orleans, 1913-1920; professor of pharmacology at the Tufts College Medical School; fellow of the American College of Physicians and the American Association of Anatomists; physiologist to the Forsyth Dental Infirmary; aged 55; died, June 30.

Charles Fremont Dight, Minneapolis; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1879; formerly health officer of Holton, Mich.; at one time assistant to the professor of pathology and the practice of medicine and clinical medicine and secretary of the faculty, University of Michigan Medical School, Ann Arbor, and instructor in pharmacology and lecturer in pharmacology and materia medica, University of Minnesota Medical School; aged 81; died, June 20, in the Franklin Hospital of coronary disease and arteriosclerosis.

Joseph Aloysius Lanahan @ New York; Albany (N. Y.) Medical College, 1899; at one time instructor in dermatology at his alma mater; served during the World War; superintendent of the New York City Hospital, Welfare Island; formerly superintendent of the Lincoln Hospital, Morrisania City Hospital and the psychiatric division, Bellevue Hospital, New York, and the Kings County Hospital, Brooklyn; aged 65; died, June 2, of coronary thrombosis.

Claude Edward Cooper @ Denver; Gross Medical College, Denver, 1900; professor of otolaryngology at the University of Colorado School of Medicine; member of the American Academy of Ophthalmology and Oto-Laryngology and the American Laryngological, Rhinological and Otolological Society; veteran of the Spanish-American War; aged 59; on the staff of the Mercy Hospital, where he died, June 21, of pulmonary tuberculosis.

Claude Marion Bloss @ Okemah, Okla.; University of Texas School of Medicine, Galveston, 1908; secretary-treasurer and past president of the Okfuskee County Medical Society; county superintendent of health; formerly member of the school board; served during the World War; on the staff of the Clinic Hospital; aged 60; died, June 14, in the Okmulgee (Okla.) Hospital following an operation for intestinal obstruction.

Charles C. Stephenson, Los Angeles; Kentucky School of Medicine, Louisville, 1889; veteran of the Spanish-American War; at one time professor of ophthalmology, College of Physicians and Surgeons, Little Rock, Ark.; past president of the Arkansas Medical Society; formerly on the staff of the Arkansas State School for the Blind, Little Rock; aged 74; died, June 12, of lobar pneumonia and chronic myocarditis.

George Lally Curran @ North Adams, Mass.; University and Bellevue Hospital Medical College, New York, 1911; fellow of the American College of Surgeons; served during the World War; surgeon to the North Adams Hospital; member of the associate staff of St. Luke's Hospital, Pittsfield, and consulting surgeon to the W. B. Plunkett Memorial Hospital, Adams; aged 50; died, June 30, of cerebral hemorrhage.

Charles Dudley Eldred @ Joliet, Ill.; Northwestern University Medical School, Chicago, 1914; fellow of the American College of Surgeons; served during the World War; past president of the Will-Grundy County Medical Society; sur-

geon to St. Joseph's and Silver Cross hospitals; aged 51; died, June 25, in St. Luke's Hospital, Chicago, of cholelithiasis, common duct stone and acute pancreatitis.

John Horn, New York; University of the City of New York Medical Department, 1885; member of the Medical Society of the State of New York and the American Laryngological, Rhinological and Otolological Society; fellow of the American College of Surgeons; formerly on the staff of the Lenox Hill Hospital; aged 82; died, June 12, of arteriosclerosis.

Carl Philip Schoen @ New Albany, Ind.; University of Louisville (Ky.) School of Medicine, 1926; fellow of the American College of Surgeons; clinical associate in gynecology at his alma mater; on the staff of St. Edward's Hospital; aged 36; died, June 9, in the New England Deaconess Hospital, Boston, following an operation for tumor of the brain.

William Martin Hill, Noank, Conn.; University of Virginia Department of Medicine, Charlottesville, 1897; member of the Connecticut State Medical Society; past president of the New London County Medical Society; on the staff of the Home Memorial Hospital, New London; aged 69; died, June 8, of coronary thrombosis.

Beverley Tucker @ Colorado Springs, Colo.; University of Virginia Department of Medicine, Charlottesville, 1889; fellow of the American College of Surgeons; attending obstetrician to the Glockner Hospital; member of the staff of the Beth-El General Hospital; aged 71; died, June 2, of coronary thrombosis.

Floyd Nicholson Shipp, Goodrich, Texas; Central College of Physicians and Surgeons, Indianapolis, 1903; member of the State Medical Association of Texas; served during the World War; at one time a member of the U. S. Public Health Service; aged 59; was killed, June 15, in an automobile accident.

Ross Chauncey Whitman, Boulder, Colo.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1899; formerly secretary and professor of pathology at the University of Colorado School of Medicine, Denver; aged 65; died, June 5, in the Community Hospital of coronary thrombosis.

James Andrew Bline @ Yakima, Wash.; Chicago College of Medicine and Surgery, 1910; member of the Pacific Coast Oto-Ophthalmological Society; on the staffs of St. Elizabeth's Hospital and the Yakima County Hospital; aged 60; died, June 21, of pneumococcal septicemia.

William Percival Ross, Battle Lake, Minn.; University of Manitoba Faculty of Medicine, Winnipeg, 1923; member of the Minnesota State Medical Association; medical superintendent of the Otter Tail County Sanatorium; aged 45; died, June 25, of coronary thrombosis.

Warren Coleman @ Troy, Ohio; Medical College of Ohio, Cincinnati, 1888; fellow of the American College of Surgeons; chairman of the county board of health; on the staff of the Stouder Memorial Hospital for many years; aged 72; died, June 11, of chronic myocarditis.

Frank Edwin Tasker, West Acton, Mass.; Dartmouth Medical School, Hanover, N. H., 1893; member of the Massachusetts Medical Society; for many years a member of the board of health; aged 74; died, June 19, of arteriosclerosis and chronic endocarditis.

Winborne Dewey Evans @ Camden, N. J.; Jefferson Medical College of Philadelphia, 1925; on the staff of the Cooper Hospital; aged 38; died, June 26, in the Zurbrugg Memorial Hospital, Riverside, of a skull fracture received in an automobile accident.

Charles J. Ennis, Sault Ste. Marie, Mich.; Schools of Surgery, Royal College of Surgeons in Ireland, Dublin, 1874; member of the Michigan State Medical Society; past president of the Upper Peninsula Medical Society; aged 88; died, June 11, of myocarditis.

James Walter Allen, Rutherford, Tenn.; University of Nashville (Tenn.) Medical Department, 1900; member of the Tennessee State Medical Association; bank president; aged 64; died, June 2, in the Baptist Hospital, Memphis, of coronary occlusion.

Albert Claire Gray, Keokuk, Iowa; Keokuk (Iowa) Medical College, College of Physicians and Surgeons, 1908; member of the Iowa State Medical Society; on the staffs of the Graham and St. Joseph's hospitals; aged 55; died, June 15, of angina pectoris.

Rollin Schwartz, Chippewa Falls, Wis.; Hahnemann Medical College and Hospital, Chicago, 1904; member of the State

Medical Society of Wisconsin; on the staff of the Chippewa County Chronic Insane Asylum; aged 58; died, June 16, of arteriosclerosis.

George P. Pennington, Atlantic City, N. J.; Jefferson Medical College of Philadelphia, 1909; for many years on the staff of the Atlantic City Hospital; aged 53; died, June 29, of cerebral hemorrhage, arteriosclerosis, heart disease and hypertension.

Daniel S. Rice • Ebensburg, Pa.; Cincinnati College of Medicine and Surgery, 1884; fellow of the American College of Surgeons; was a member of the local examining board during the World War; aged 78; died, June 18, of myocarditis and endocarditis.

Austin Keeler Van Dusen • Chicago; Northwestern University Medical School, Chicago, 1923; clinical assistant in pediatrics at his alma mater, 1930-1933; on the staff of the Illinois Masonic Hospital; aged 39; died, June 22, of coronary occlusion.

George Lawrence Stevenson, Sacramento, Calif.; University of California Medical Department, San Francisco, 1899; member of the California Medical Association; aged 67; died, June 24, of carcinoma of the lip with metastasis to the lungs and liver.

Nathaniel J. Pickett, Milford, Texas; University of Tennessee Medical Department, Nashville, 1892; member of the State Medical Association of Texas; past president of the Ellis County Medical Society; aged 70; died, June 20, of uremia.

Silas Sanford, Palmyra, Mo.; Bellevue Hospital Medical College, New York, 1886; member of the Missouri State Medical Association; past president of the school board; aged 78; died, June 25, in Rochester, Minn., of carcinoma of the stomach.

Chester Earl Myers, North Freedom, Wis.; University of Nashville (Tenn.) Medical Department, 1911; member of the State Medical Society of Wisconsin; aged 55; died, June 29, of pneumonia, coronary disease, hypertension and nephritis.

Foy Clawson Payne • Dayton, Ohio; University of Cincinnati College of Medicine, 1917; member of the American Society of Clinical Pathologists; on the staffs of St. Elizabeth and Good Samaritan hospitals; aged 43; died, June 15.

Annetta Ayers Saunders • Chicago; National Homeopathic Medical College, Chicago, 1896; Harvey Medical College, Chicago, 1897; Dunham Medical College, Chicago, 1899; aged 76; died, June 20, of chronic myocarditis and nephritis.

David C. Homan, Oglesby, Texas; Baylor University College of Medicine, Dallas, 1908; member of the State Medical Association of Texas; past president of the Coryell County Medical Society; aged 55; was shot and killed, June 4.

Benjamin F. Harden • Wellsburg, W. Va.; Jefferson Medical College of Philadelphia, 1881; past president of the Brooke County Medical Society; bank president; aged 81; died, June 2, of carcinoma of the pancreas.

Robert Lee Riley, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1884; aged 75; died, June 21, in the Mercy Hospital of shock and hemorrhage following an operation for abdominal cyst.

John Henry Belt, Merritt Island, Fla.; Bellevue Hospital Medical College, New York, 1867; Civil War veteran; aged 94; died, June 21, in the Veterans Administration Facility, Bay Pines, of uremia and nephrosclerosis.

Dayton Davis Stone • Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1910; on the staff of the Highland Park General Hospital; aged 50; died, June 29, of coronary thrombosis.

Daniel Vincent O'Donnell • Bennington, Vt.; University of Vermont College of Medicine, Burlington, 1904; on the staff of the Henry W. Putnam Memorial Hospital; aged 58; died, June 18, of heart disease.

Jesse Johnson Willingham • State Sanatorium, Ark.; Rush Medical College, Chicago, 1897; on the staff of the Arkansas Tuberculosis Sanatorium; aged 71; was accidentally drowned, June 30, while fishing.

Edward Maupin Gayle, Portsmouth, Va.; University of Virginia Department of Medicine, Charlottesville, 1902; formerly on the staff of the Parrish Memorial Hospital; aged 60; died, June 22, of heart disease.

J. W. Robinson, Medford, Ore.; Willamette University Medical Department, Portland, 1878; formerly mayor of Jacksonville; aged 88; died, June 23, in the Community Hospital of pulmonary edema.

Lewis Edward Kelly, Berkeley, Calif.; Hahnemann Medical College of Philadelphia, 1876; Civil War veteran; aged 94; died, June 4, of bronchial pneumonia, arteriosclerosis and chronic myocarditis.

Frank Victor Johnson • Maquoketa, Iowa; Bennett College of Eclectic Medicine and Surgery, Chicago, 1897; aged 68; died, June 2, in the Finley Hospital, Dubuque, of carcinoma of the lung.

Clinton Elmer Hunter, Jennings, La.; Chicago Homeopathic Medical College, 1901; aged 72; died, June 1, in a hospital at Lake Charles of carcinoma of the cecum and ascending colon.

Charles Bruce Walls, Chicago; Chicago Homeopathic Medical College, 1894; aged 81; died, June 24, in the Veterans Administration Facility, Hines, Ill., of bilateral pyelonephritis.

Najib Nassif Sallume, Toledo, Ohio; Baltimore Medical College, 1896; member of the Ohio State Medical Association; aged 69; died, June 30, of coronary occlusion and vascular sclerosis.

Solon L. Coleman, Uniontown, Ala.; Tulane University of Louisiana School of Medicine, New Orleans, 1898; aged 64; died, June 4, in a hospital at Selma, of cerebral hemorrhage.

Oscar Lee Bailey • Ocean Springs, Miss.; St. Louis College of Physicians and Surgeons, 1892; for many years bank president; aged 68; died, June 21, of carcinoma of the pancreas.

Juba Everett Pickering, Brooklyn; College of Physicians and Surgeons, Baltimore, 1908; served during the World War; aged 58; died in June as the result of slashing his wrists.

Milton Louis Brenner • Houston, Texas; Tulane University of Louisiana School of Medicine, New Orleans, 1918; aged 45; died, June 21, of uremia and heart disease.

Louis Bartholomew Niquette, Northampton, Mass.; University of Vermont College of Medicine, Burlington, 1880; aged 80; died, June 16, of chronic myocarditis.

Dominic P. Thill • Milwaukee; Milwaukee Medical College, 1900; aged 67; died, June 8, in St. Joseph's Hospital of coronary occlusion, myocarditis and hemiplegia.

Moses Malcolm Knoller, Brooklyn; Long Island College Hospital, Brooklyn, 1909; member of the Medical Society of the State of New York; aged 51; died, May 23.

Burton George Mead Robinson, Washington, D. C.; Howard University College of Medicine, Washington, 1911; aged 58; died, June 5, of gastric carcinoma.

Byron N. E. Spees, Glenns Valley, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1891; aged 70; died, May 4, in St. Francis Hospital, Beech Grove.

Frank E. Wilson, Jeffersonville, Ohio; Hahnemann Medical College and Hospital of Philadelphia, 1891; aged 70; died, June 7, in St. Paul of cerebral hemorrhage.

Fannie Kimball Fiester, Austin, Minn.; Woman's Medical College, Chicago, 1891; Hahnemann Medical College and Hospital, Chicago, 1893; aged 71; died, May 6.

Stanley O. Newcomb • Ida, Mich.; Detroit College of Medicine, 1904; veteran of the Spanish-American War; aged 61; died, June 27, of coronary thrombosis.

William Allen Cathcart, Wallaceburg, Ont., Canada; University of Toronto Faculty of Medicine, 1915; aged 46; was killed, June 7, in an automobile accident.

Harriet E. Adams, Horton, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1894; aged 71; died, June 15, of myocarditis.

Luzerne Coville, Arlington, Va.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1889; aged 72; died, June 23.

Charles F. Otis Sr., Rochester, N. Y.; Hahnemann Medical College and Hospital, Chicago, 1882; aged 78; died, June 12, at his home in Honeoye Falls.

James Michael Glynn, Chicago; Rush Medical College, Chicago, 1892; member of the Illinois State Medical Society; aged 71; died, July 3, of uremia.

William Everett Long, Buffalo; Homeopathic Hospital College, Cleveland, 1880; aged 79; died, June 8, in the Millard Fillmore Hospital of uremia.

William James Kerr, Oakland, Calif.; University Medical College of Kansas City, 1900; aged 59; died, June 11, of coronary thrombosis and diabetes.

Willis Isaac Purdy • Middletown, N. Y.; University of the City of New York Medical Department, 1882; aged 84; died, June 5, of arteriosclerosis.

Clayton P. House, Oroville, Wash.; University of Vermont College of Medicine, Burlington, 1881; aged 80; died, June 13, in a hospital at Medical Lake.

Johann Hermann Meyer, San Bernardino, Calif.; Jefferson Medical College of Philadelphia, 1901; served during the World War; aged 60; died, June 26.

William Jackson Bolton, Washington, D. C.; College of Physicians and Surgeons, Baltimore, 1892; aged 67; died, June 18, in the Casualty Hospital.

Lemuel E. Davies, Miami, Fla.; Hahnemann Medical College and Hospital of Philadelphia, 1896; aged 69; died, June 16, of cerebral hemorrhage.

Edgar Gilmore Givhan, Montevallo, Ala.; Medical College of Alabama, Mobile, 1894; aged 67; died, June 3, of carcinoma of the prostate.

John T. Barnett, Jonesboro, Ind.; Kentucky School of Medicine, Louisville, 1882; aged 80; died, June 30, of chronic myocarditis and nephritis.

Clarence Winfield Pierce Foss, Brunswick, Maine; Medical School of Maine, Portland, 1895; aged 68; died, June 22, of coronary occlusion.

John C. Travers, Baltimore; University of Maryland School of Medicine, Baltimore, 1895; aged 65; died, June 11, of coronary thrombosis.

George Ignatius Lythcott, Tulsa, Okla.; Boston University School of Medicine, 1913; served during the World War; aged 52; died, May 1.

Thomas I. Marks, Halsey, Ore.; University of Oregon Medical School, Portland, 1896; aged 67; died, June 16, of coronary thrombosis.

Oscar F. Plummer, Macon, Ill.; St. Louis College of Physicians and Surgeons, 1903; aged 67; died, June 14, of cerebral hemorrhage.

William Everett Jonah, Atlantic City, N. J.; Medical School of Maine, Portland, 1900; aged 64; died, June 8, of coronary occlusion.

Wilfred Kennedy Keith, Creston, Iowa; Rush Medical College, Chicago, 1894; aged 66; died, June 30, in Los Angeles, of angina pectoris.

Joseph Hooker Callbreath, Encanto, Calif.; Long Island College Hospital, Brooklyn, 1890; aged 74; died, June 2, of cerebral softening.

George Stewart Allen, Mackinaw, Ill.; Rush Medical College, Chicago, 1902; also a dentist; aged 70; died, May 5, of heart disease.

Annie Amelia Backus, Port Rowan, Ont., Canada; Hahnemann Medical College and Hospital, Chicago, 1889; aged 75; died, June 16.

Albert I. Babendreer, Ocean Springs, Miss.; Pulte Medical College, Cincinnati, 1899; aged 70; died, June 20, of mediastinitis.

Harrison Thomas Healy, New Bedford, Mass.; Baltimore Medical College, 1907; aged 55; died, June 1, of chronic myocarditis.

H. A. J. Watkins, Magee, Miss.; University of Louisiana Medical Department, New Orleans, 1883; aged 85; died, May 7, in Jackson.

James B. Nash, University City, Mo.; St. Louis College of Physicians and Surgeons, 1901; aged 63; died, June 14, of nephritis.

Charles Edward Gardiner, Brooklyn; Long Island College Hospital, Brooklyn, 1899; aged 61; died, June 15.

Walter Lee Dodson, Reform, Ala.; Medical College of Alabama, Mobile, 1906; aged 59; died, June 16.

George H. Harbarger, Coalton, Ohio; Ohio Medical University, Columbus, 1893; aged 66; died, June 17.

Burley Carl Bain, Bentonville, Ark. (licensed in Arkansas); aged 68; died, June 16, of myocarditis.

Frederick Winnett, Toronto, Ont., Canada; Trinity Medical College, Toronto, 1886; died, June 16.

Pinckney K. Carson, Hohenwald, Tenn. (licensed in Tennessee in 1889); aged 82; died, May 20.

Junius M. Armstrong, Garland, Texas; Dallas Medical College, 1903; aged 56; died, May 25.

Erastus A. Tuttle, Englewood, Colo. (licensed in Colorado in 1900); aged 89; died, June 28.

Oscar Louis Lennard, Atoka, Okla. (licensed in Oklahoma in 1935); aged 60; died, June 17.

Bureau of Investigation

A FRAUDULENT GALLSTONE CURE

The Home Drug Company of Minneapolis Declared a Fraud and Debarred from the Mails

A Minnesota quack, one Bert Victor Lares, M.D., has for some years conducted a fraudulent medical mail-order business known as the Home Drug Company. In spite of the fact that the Food and Drug Administration in 1935 prosecuted and fined Lares' company and declared his "gallstone cure" a fraud, and in spite of the further fact that in 1936 the Federal Trade Commission proceeded against the Home Drug Company, the business continued until November 1937, at which time the Post Office Department issued a fraud order against the Home Drug Company and its officers and agents.

B. V. Lares, according to the records of the American Medical Association, was born in New Hampton, Iowa, in 1874 and holds a diploma from the University of Minnesota College of

GALL STONE COLIC

Doctor's Private Prescription
Gives Marvelous Results

SHE WANTS OTHER WOMEN TO KNOW HER COMFORT

"After suffering for seven years with gall bladder and liver trouble and having tried several different kinds of medicine without relief I was told to have an operation. I did not want one until I had tried everything for gall stone trouble. My aunt recommended your Prescription No. 69, and after the first bottle I felt a great change. Since taking the treatment, words cannot express how thankful I am. I am telling this for the benefit of other sufferers. If you want relief, get this doctor's prescription. It will save you money and give you new life."

Avoid operations. Treat the cause in a sensible, painless, inexpensive way at home with a recognized practicing specialist's prescription for liver, gall bladder and stomach trouble which have given gratifying results for 28 years. Write for Free Literature to

HOME DRUG CO.,
18-P N. 4th St., Minneapolis, Minn.

Homeopathic Medicine and Surgery, issued in 1900. For some reason not clear, the state of Minnesota granted Lares a license to practice medicine in 1897—three years before he is shown to have received his diploma. The medical directories show Lares in St. Paul in 1900, in Maple Plain, Minn., in 1902 and 1904, in Delano, Minn., from 1906 until 1918, and at Minneapolis from 1921 to date.

The Home Drug Company was started in 1926 by Lares and a former advertising man, one D. A. Lundy. Each put in \$100 to start the company. Four years later, in 1930—so profitable is mail-order quackery—the enterprise was incorporated under the laws of South Dakota with a capitalization of \$100,000, the stock, according to the report of the Post Office Department, being held by Lares and Lundy and their respective wives! Lares was president of the concern and Mrs. Lares vice president, while Lundy was secretary-treasurer and advertising manager. Lares' scheme was to advertise that he had a cure for gallstones, a medicine that he called "Prescription No. 69" and which, he declared, would "dissolve" gallstones. In his advertisements he also declared that Prescription No. 69 was the prescription of a physician who had for years specialized in gallbladder disease.

During the hearing at Washington, Lares testified that he took a three year homeopathic course in the University of Minnesota College of Homeopathic Medicine and Surgery,

although he admitted that he had never been graduated by a high school. Lares' evidence at the hearing demonstrated that the man was in no sense of the word a specialist in diseases of the liver and gallbladder and that such few cases of that kind as he had were quite incidental to the general practice in which he had been engaged. In 1917 Lares secured a commission as first lieutenant in the Medical Corps of the United States Army and served therein, without reaching the front, for a period of about eighteen months, during the course of which he was advanced to a captaincy. He admitted that he did not treat a single case of gallstones during this period but that his duties consisted of training stretcher-bearers, performing vaccinations and inoculations, prescribing for constipation, and so on.

In 1919 Lares again entered general practice, this time in Minneapolis. In 1921 Minneapolis and St. Paul papers reported that Lares had been arrested following the death of a 21 year old girl who was said to have died from peritonitis following an alleged illegal operation. Lares was later released, according to the Post Office report. On a later date Lares was again arrested, found guilty and fined on charges of "compounding without a registered pharmacist."

The memorandum of Judge Karl A. Crowley, Solicitor for the Post Office Department, to the Postmaster General, recommending the issuance of a fraud order, shows that while the Home Drug Company was prosecuted in September 1935 under the National Food and Drugs Act for making fraudulent therapeutic claims for its Prescription No. 69, found guilty and fined \$50, and while in February 1936 the Federal Trade Commission ordered the Home Drug Company to cease representing that Prescription No. 69 was an effective remedy for gallstones, nevertheless the Home Drug Company continued to advertise that its "patent medicine" would cure gallstones. The explanation may lie in the further fact that the evidence in the case also showed that the receipts of the Home Drug enterprise at the time of the hearing approximated \$27,000 annually!

As an interesting sidelight, Lares was said to have testified at the hearing that, since the company had been formed, it had expended large sums for attorneys' fees "in an effort to avoid adverse action by the Federal Trade Commission and other governmental agencies." It is a well known fact that it is not uncommon for men who, having previously as government officials had to prepare cases against fraudulent mail-order concerns later would leave the government service and set up as "experts" in dispensing information—for a fee—which would show concerns how to skate on as thin ice as possible without breaking through.

When "Prescription No. 69" was analyzed by the federal chemists in preparation for the case of the Food and Drug Administration against the Home Drug Company, the chemists reported that the stuff "consisted essentially of glycerin, with small proportions of oxgall and bile acids." According to the alleged formula furnished by Lares to the Post Office Inspector, Prescription No. 69 contained very small quantities (homeopathic?) of chelidonium, chionanthus, cinchona, colocynth, dioscorea, hydrastis, iris, leptandra, podophyllum, bile salts and strychnine. Lares' concern also put out a pill that it called "Laxative Triangles" and which contained phenolphthalein, bile salts and cascara.

While Lares' lawyers contended that the Home Drug Company treatment was "based on homeopathy," the facts were that it was the veriest mongrel—neither homeopathic nor scientific in character. According to Lares' testimony, his idea in mixing up his medicines was "to put all possible remedies that his patients would likely be needing later into a single mixture." He based this on the interesting, if not convincing, theory that "only the drug particularly indicated would act at a given time and that, when the indications for that particular substance had passed, its action would cease and the other drugs in the preparation would thereon rotate and come into play successively as needed." Thus Lares, in order to justify his quackery, endowed his conglomerate mixture of homeopathic and other drugs with more than human intelligence. At the time of the hearing Lares was asked why, if his theory was good, it would not be simpler

to make a mixture of all the drugs in the homeopathic armamentarium, so that every disease imaginable could be properly treated as the occasion arose! Lares opined, however, that such a pill would "take too much room" and characterized the inquiry as "traveling into the ridiculous." It obviously depended on whose ox was gored.

Lares testified at the hearing also that his so-called treatment was directed solely to the "symptoms" of gallstones and other ailments so fluently described in his advertising, and he volunteered that, when prescribing homeopathically, "I don't care whether it is cirrhosis of the liver or ingrowing toe-nails."

On November 15 Judge Crowley declared that the evidence showed the business of the Home Drug Company to be a scheme for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises, and recommended that a fraud order be issued. On November 17 Postmaster General Farley issued the fraud order.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

DANDRUFF

To the Editor:—What is considered the most efficient method for the treatment of dandruff?
H. F. SCHROEDER, M.D., Marinette, Wis.

ANSWER.—Dandruff is the popular name for fine exfoliation that occurs in seborrhea sicca of the scalp. Once the disease is arrested, it usually requires continued attention over a further period to prevent recurrence.

The scalp should be kept clean by washing with soap and water sufficiently often to keep it clean. The more oily the scalp, the more frequently should it be washed. No more definite rule for frequency can be framed. The average man's scalp may be safely washed every week and many as often as twice a week or oftener. Frequently an accompanying itching of the scalp yields to mere washing. For severe seborrhea with crusting, oil cleansings are more satisfactory.

If there are any indications for systemic treatment, these, of course, should be met. An anemia may require iron or liver; an imperfect digestion needs attention; and always the bowels should be regularized.

Of the many local remedies for seborrhea of the scalp, not one is more useful than sulfur. It is best used in the form of a pomade, at least at the beginning of treatment. Wool fat, lard, petrolatum or cold cream may be used by themselves or in combination as bases. They can be softened by the addition of oil. The objections to their use is that they grease the hair excessively and they do not wash easily from the scalp. Usually the patient applies too much material, more than is necessary, and is careless in getting it on the hair. An oil shampoo before the use of soap and water facilitates removal. There are more elegant menstrooms on the market in the form of oils, but these cost more and are not essential. Sulfur may be used in the form of solution of sulfured lime (Vlemingck's solution) diluted to fit the circumstances. In the beginning the scalp can accommodate a mixture of one part of the solution to seven of water. This can later be given less diluted and a few can stand a full strength solution. It is best applied with a medicine dropper before retiring, less often when the scalp condition is improved.

Mercury in various forms is excellent. The official ammoniated mercury ointment may be used or mixed with an equal or twice its quantity of base. Mercury bichloride is excellent in lotions. It may be used in the proportion of 1 in 1,000 to 1 in 10,000. The addition of salicylic acid and resorcinol increase the value of these lotions. Resorcinol should not be used on blond or red hair.

Ultraviolet rays are sometimes useful for seborrhea of the scalp. It is not necessary to produce an erythema. The scalp should be washed before exposures to facilitate the penetration of the rays. Massage has been lauded by some as improving the circulation of the scalp, but its capacity for good is doubtful.

ANGIOMA OR CIRSOID ANEURYSM OF SCALP

To the Editor.—A woman aged 35, in good health, has for the last twelve years had hemorrhages from the scalp just above and in back of the left ear. These hemorrhages have been profuse and were easily stopped by coagulation of the bleeding point by means of diathermy. Since the last coagulation several weeks ago, the posterior auricular artery has dilated considerably from a point midway between the cartilage of the ear and the left mastoid. This dilatation is more pronounced as it proceeds up to the scalp. There is redness of the skin underlying the distal part. Pulsations are not only easily felt but easily seen. At times the patient feels as though there were a veil passing over the left eye, but this is only momentarily. Would it be wise to ligate this vessel at its origin or between the mastoid and cartilage of the ear? M.D., Wisconsin.

ANSWER.—The changes in the skin, the dilatation of the posterior auricular artery and the location of the diseased area suggest a diagnosis of some easily bleeding tumor such as an angioma or a cirsoid aneurysm. The latter occurs on occasion in the scalp in this area.

Raymond W. McNealy has written an excellent article on aneurysms of this nature in Dean Lewis's *Practice of Surgery* (Hagerstown, Md., Prior & Co., 1932, vol. 12, chapter 5, section 4, pp. 101-157). It would appear that the condition is due to an abnormal communication between veins and arteries. This may take place in a number of different ways and from different causes such as from a nevus or telangiectasis, from a deep congenital anomaly of the blood vessels (deep nevus), from a single severe trauma, or from a number of minor traumas.

There is present in these tumors a tortuous mass of dilated vessels beneath the scalp. The overlying skin is congested and there is not only a thrill but an auscultatory murmur. Spontaneous bleeding such as described is not often a symptom. There are many procedures aimed at cure. McNealy states that a modern standard procedure would be more or less as follows: (1) ligation of the external carotid artery, (2) ligation of the secondary trunks such as the temporal, occipital and auricular arteries, (3) ligation of the main trunks at the edge of the mass, and (4) extirpation of the mass following its reduction in size because of the procedures listed.

The information given does not enable an accurate diagnosis, but it would appear that cirsoid aneurysm is a likely cause of the difficulty. There is another possibility and that is a traumatic aneurysm due to a weakening of the wall of the artery following diathermy.

In this case ligating the artery distally and proximally to the dilatation would probably be sufficient to end the difficulty. Radiation therapy is not apt to succeed if the vessels involved are large. Injection therapy has been largely abandoned.

The cause of the original hemorrhages over a period of years from the scalp remains obscure in the absence of more detailed information.

HERNIA DEVELOPING IN ATHLETE

To the Editor.—A physician aged 53, a former athletic director, performed many heavy athletic duties, including wrestling and heavy lifting, up to several years ago. While he was lifting a heavy object about a week ago an inguinal hernia occurred. Could there be an inherited weakness in this region? If so, how could he have performed for many years such strenuous athletic work without any such occurrence? The hernia is small and not troublesome to any extent. What treatment is advisable?

S. A. KLEGER, M.D., Astoria, Ore.

ANSWER.—The development of an indirect inguinal hernia is usually due to the failure of obliteration of the peritoneal process extending to or in continuity with the processus vaginalis of the testicle. At times this patency is limited to a slight funnel shaped dimpling of the peritoneum at the internal ring which is fixed by the obliterated portion extending into the cord.

Not infrequently there is an associated weakness of the structures of the abdominal wall medial to the internal ring and when associated with a patent peritoneal process and increased abdominal pressure a hernia early in life usually results. Occasionally muscle weakness alone may predispose to a hernia at the internal ring.

There are several factors which tend to delay the development of an indirect hernia in the presence of some inherited or acquired weakness: (1) when the neck of the sac at the internal ring is unusually small; (2) when the abdominal muscles are well developed by inheritance or through progressive physical activity, so that the internal ring is well protected at all times; (3) the absence of extreme or prolonged intra-abdominal pressure or debilitating illness or a combination of these factors, with good muscle defense.

There are other factors which tend to predispose to the late development of an indirect hernia: 1. Usually and normally there is a decrease in physical activity and muscle strength. This may start before the age of 30 as the result of a sedentary

occupation but usually takes place to some extent by 40, and almost invariably at 50. 2. The frequent increase in weight in men after 25 or 30 and especially after 50 increases the intra-abdominal tension but also is almost constantly associated with some decrease in muscle strength and tone at the internal ring. 3. Following a decrease in muscle strength and tone, any unusual increase of abdominal pressure such as lifting a heavy object, a sudden strain or effort, a chronic cough and other factors may overcome the protective muscle defense at the internal ring and initiate a hernia.

In the instance in question there may have been a slight or even a considerable patency of the peritoneal process which was attached to its obliterated portion in the cord at the internal ring. Good muscle development and tone protected the internal ring during the years of strenuous activity. Several years after giving up these activities and following a severe effort or strain, this patient had a hernia. Lack of muscle defense at the vulnerable internal ring probably resulted from lessened activity and from increased age.

In the absence of contraindications, the hernia should be operated on without unnecessary delay. Otherwise a properly fitting truss should be worn.

POSSIBLE MILIUM CONGENITALE IN INFANT

To the Editor.—A baby, aged 10 weeks, for two weeks has had minute nonitching vesicles over the face, scalp, anterior part of the neck and upper anterior part of the chest. They appear to be in the skin but do not break. Those on the chest are surrounded by a small areola of red but elsewhere do not appear to be associated with much inflammatory reaction. The baby is on a formula of Karo, partly skimmed milk and water, with orange juice and cod liver oil in the usual quantities, and is doing well from a nutritive standpoint. He is bathed with Ivory or castile soap and the creases are oiled with Mennen's Baby Oil. I know of no material that comes in contact only with the skin area mentioned. Cod liver oil is now being omitted from the diet. Orange juice was omitted for one week without results. The baby is on small doses of ultraviolet rays for want of something better to do. I dislike changing the entire formula unless necessary, as in the first few days of the baby's life I had a hard time getting the digestive system oriented when the mother's milk failed.

M.D., New York.

ANSWER.—The lesions on this newborn infant's skin, from the description, might well be milium congenitale. Milia are small whitish nodules in the skin, especially of the face. They are usually retention cysts of the sebaceous glands or hair follicles. The lesions may be present at birth and occur on the scalp and face. They are reddish, pale red-yellow or yellow lesions and vary from pinpoint sized papules to well defined patches. Crocker, who described this condition, believed that the lesions were the result either of miscarried embryonic epithelium or of the adherence of the amnion at an early stage of fetal life. An excellent illustration of milium congenitale in a newborn infant, taken from the collection of C. Leiner, may be found in Pfaunder and Schlossmann's *Handbuch des Kinderheilkunde*, fourth edition, volume 10, "Die Hautkrankheiten des Kindesalters" (Berlin, F. C. W. Vogel, 1935, p. 267). The infant's diet need not be altered, as the lesions would not be affected by changes in food.

ELECTRIC MASKS FOR HAY FEVER

To the Editor.—I have noticed numerous advertisements of various masks with electric batteries, also numerous other gadgets to insert into the nostrils for the control of hay fever. Will you kindly discuss the relative merits, if any, of these contraptions?

W. E. DELICATE, M.D., Edwardsville, Ill.

ANSWER.—A device of the aforementioned description, called the Allergy Electric Mask, has been placed on the market by the Allergy Research Institute of Cincinnati. This device consists of a double wall metal cup, perforated to permit passage of air and by means of a soft rubber face piece fitting tightly over the mouth and nostrils. It is held there by ribbons which tie around the head. Between the two walls is placed a filtering paper. The positive pole is connected to one metal cup and the negative to the other cup. Claims are made that the pollen particles are precipitated by the potential on the charged plates. Those particles that are not caught by means of the electrostatic precipitating process are trapped by means of the paper filters.

Insufficient critical evidence has been made available to substantiate the claim that a potential of $1\frac{1}{2}$ volts produces a force of sufficient strength to attract particles and hold them, to be of any great value in the removing of pollen for hay fever relief. To filter efficiently by the Cottrell process of electrostatic precipitation, potential of several thousand volts is required to attract the pollen particles and hold them to

the plates. It is possible that what filtering efficiency this mask may have is due largely to the filter paper between the two charged plates. It is probable that, if the patient is willing to wear the mask, a considerable portion of the pollen will not reach the mouth or nostrils. There is, however, another port of entry for pollen, namely the eyes; hence the wearing of this mask is no assurance that the patient will obtain relief from hay fever symptoms. Furthermore, unless the patient is careful, leaks occur between the skin and the rubber, thereby reducing the efficiency of the mask.

PROBABLE NEUROSYPHILIS: TREATMENT

To the Editor:—A white man aged 50, a cook, married but without children, contracted syphilis in 1918 while in the navy. He received three intravenous injections and several in the hip. For about two years he took some form of mercury pills. The patient felt perfectly well until about two years ago, when he began to complain of impairment of memory, irritability and a peculiar sense of pressure along the upper part of the spine. I first saw him in March 1938. He was well developed, was 66½ inches (168 cm.) tall and weighed 164 pounds (74 Kg.). There was no apparent heart lesion, the blood pressure was 144 systolic and 88 diastolic, the Kahn reaction was 4 plus, and urine and Romberg tests were negative. The tendon reflexes were hyperactive. The pupils were markedly miotic. The ophthalmologist found visual acuity normal and the visual field restricted in the temporal palpebral quadrants. The optic nerve was slightly affected, and blood vessels showed moderate arteriosclerosis. There were some areas of chorioretinitis in all stages from old to new. The patient has been treated with bismarsen intramuscularly weekly for five weeks, the first injection being 0.1 Gm. and the following four injections 0.2 Gm. He then received 0.2 Gm. every fourth day and has had a total of ten injections to date. He also had 10 minims (0.6 cc.) of potassium iodide three times a day for two weeks, rest for one week, and then a repetition of the treatment. His Kahn reaction is still 4 plus. His urine has been normal. Subjectively he has improved in that his memory is better, he is not irritable, he says he has more "pep," and the sense of pressure in the spine has left him. Contraceptives have been used and the wife has never been pregnant. Will you kindly outline a course of treatment? Probably you will suggest a spinal fluid examination. If positive, how would this affect the treatment?

M.D., Maine.

ANSWER:—From the data furnished it would seem that the patient has neurosyphilis, and in view of this it would be advisable to examine his spinal fluid immediately. This would be done not only to confirm the impression that the infection has invaded the nervous system but also to determine the character of the spinal fluid involvement. The loss of memory and irritability suggest, of course, that the patient may be in an early phase of dementia paralytica. The eye condition might well represent a complication of the syphilis, and it would seem advisable to continue with arsphenamine, bismuth and potassium iodide before changing the program of treatment. Neoarsphenamine or arsphenamine should be given for a series of approximately ten injections in conjunction with at least twenty injections of a bismuth compound and potassium iodide by mouth. At the end of this treatment the spinal fluid should be reexamined and, if there is not any material change in it, it would seem that the patient would be a candidate for fever therapy, particularly if he manifests the parietic type of spinal fluid. The treatment outlined would tend to prevent complications in the visual tract from fever therapy. The treatment subsequent to the malarial course must be guided by the response the patient makes to fever therapy, but in all probability further treatment with arsphenamine and a bismuth compound will be necessary approximately three months after the fever course. In view of the condition of the eye it would be inadvisable to give tryparsamide.

WOOL FAT AND LIQUID PETROLATUM FACE CREAMS

To the Editor:—Please discuss wool fat and liquid petrolatum creams as to efficiency and danger for growing hair. How do your regard almond, olive and mineral oils for use in face creams? M.D., Maryland.

ANSWER:—Hydrous wool fat (adeps lanae hydrosus, lanolin) is obtained from the fat of sheep's wool. It resembles wax, consisting of cholesterol and ischolesterol either in free state or combined as esters of fatty acids; in this respect it differs from usual animal and vegetable fat in that it does not contain the glycerin esters of fatty acids. It has long maintained its popularity as an ingredient of pharmaceutical ointments and cosmetic creams. In cosmetic form it is highly commended as an excellent emollient. When purified it is practically inodorous, blends well with many drugs and cosmetic ingredients, and does not readily become rancid. Because of its sticky tendency, no more than from 3 to 5 per cent is used in creams, to which mineral oils are usually added for their lubricating quality. Wool fat is available in two forms, hydrous and anhydrous. Wool fat is

used in conjunction with water soluble materials and employed for pharmaceutical purposes, whereas anhydrous wool fat is used cosmetically. There is no proved tendency in wool fat toward the promotion of hair growth. It has only rarely caused allergic symptoms (Ramirez, M. A., and Eller, J. J.: The "Patch" Test in "Contact Dermatitis," *J. Allergy* 1:489 [Sept.] 1930).

Liquid petrolatum, a synonym for which is mineral oil, is derived from various forms of petroleum. It is valued for its detergent and lubricating power, which makes the oil an important ingredient of cleansing creams. Liquid petrolatum has no power of skin penetration. It will not stimulate hair growth. Its great advantage is the lack of tendency toward rancidity, because it is not a fat. Almond and olive oils, which are vegetable fats and are more emollient in action, easily become rancid and lack the detergent qualities of the mineral oils. Impurities in any of these products may cause them to be irritating. There are also rare cases of allergy. For examples see: Coca, Walzer and Thommer, "Asthma and Hay Fever in Theory and Practice," and R. P. White, "Dermatoses or Occupational Affections of the Skin," page 274.

ARSENIC AND ACUTE STUPOR

To the Editor:—A Polish laborer aged 53 was run over by an automobile while lying in the street. His past history was essentially negative except for two attacks of "grip" fifteen and eight years ago. He was seen at 6 p. m. and stated that he was in excellent health. Between that time and his death he had two beers and one shot of whisky. At about 7:15 he was said to have been staggering. At 7:45 he was run over by the automobile and witnesses claim that he was lying in the road in a stupor. Autopsy and chemical examination of the stomach revealed 23½ grains (0.15 Gm.) of arsenic in the stomach, spleen and kidney. How much arsenic is necessary to produce such an acute stupor? Please refer me to the latest literature on arsenic poisoning.

M.D., Massachusetts.

ANSWER:—The amount of arsenic necessary to produce an acute stupor varies with individuals and cannot be fixed but is usually large. The amount absorbed is the important factor. Arsenic in the stomach contents is not important from this standpoint. In the case cited no distinction is made between arsenic in the stomach (contents?) and that in the spleen and kidney. The liver, brain and kidney are the organs to examine in acute cases. The minimal fatal dose is 3 grains (0.2 Gm.) absorbed, but that amount is not adequate to produce acute stupor, which is rare under any conditions. Experimental evidence indicates that alcohol favors either the absorption or the retention of arsenic in the organs.

DANGERS OF PESSARY FOR CONTRACEPTION

To the Editor:—Is the flexible cone pessary an acceptable product and without danger to the cervix uteri as far as hemorrhage, cancer and erosion of the cervix are concerned? I have received literature on this contraceptive device. It is a pliable rustless chromium wire covered to a thickness of one thirty-second inch with soft pure rubber. I have been told that short wave diathermy treatments cannot be given to the pelvis when the Gomco contraceptive metallic chain is in the uterus. Its temperature is supposed to be raised to such an extent that it produces a burn during a short wave diathermy treatment. Would it be all right to give long wave diathermy treatments to the pelvis to a patient with the rubber coated flexible cone pessary in the cervix? M.D., Minnesota.

ANSWER:—Occasionally in selected cases of dysmenorrhea and amputation of the cervix, with obstruction of the outlet of the uterus, a cervical pessary is of distinct value. In these cases the pessary should be removed after two or three months and it may not have to be replaced. Intracervical pessaries which are used for contraceptive purposes are nearly always a menace to life and health and therefore should never be used. Many complications have arisen following their insertion, including cervical "erosions" and bleeding. It has not been proved that cancer has arisen following the use of these devices. In some cases death due to infection has resulted directly from their use. Whereas intra-uterine foreign bodies for the purpose of preventing conception are not as dangerous as intracervical appliances, they also should not be used. If these suggestions are followed there need be no fear concerning the use of short or long wave diathermy in the presence of metallic foreign bodies in the uterine or cervical canal.

RECUMBENT HYPOTENSION AND POSSIBLE
DIAPHRAGMATIC HERNIA

To the Editor:—A woman aged 49, with some of the nervous manifestations of the menopause, has a blood pressure of 180/140 in the sitting position and only 95/60 while recumbent. In spite of bromides and various sedatives, she persistently complains of insomnia because of feelings of pain around her heart, sensations of pressure in the upper part of the abdomen and gurgling of gas interpreted as borborygmi. She had a cholecystectomy two years ago, which failed to relieve the pains and discomfort in the upper part of the abdomen. She had had symptoms of spastic colitis and has been treated for this without much relief. Physical examination reveals no manifestations except visceroptosis, verified at the laparotomy two years ago, moderate obesity and tenderness all through the upper part of the abdomen and down into the left side. Laboratory tests reveal a red blood count of 2,850,000, hemoglobin 65 per cent, alcohol histamine meal showing no free acid and only 3 points of total acid, no occult blood, and several gram-negative large rod-shaped bacilli. Blood smear shows 57 per cent polymorphonuclears, 31 per cent lymphocytes and no abnormal red cells or nucleated reds. Could the pain and discomfort in the upper part of the abdomen and heart region be in any way associated with the recumbent hypotension?

W. L. SHARP, M.D., Anderson, Ind.

ANSWER.—Such variations of the arterial tension as recorded are extremely unusual. It would be interesting to know whether these violent fluctuations have been observed repeatedly and consistently or only on one occasion. The pressure of 180/140 is in itself rather unusual; a pulse pressure of but 40 mm. is small and suggests myocardial inadequacy. It is unfortunate that no mention is made of the pulse rate in the two positions or whether there is any asymmetry of the tension in the two arms.

The other clinical observations are highly suggestive of diaphragmatic herniation with intrathoracic evagination of abdominal viscera. The visceroptosis is suggestive of poor musculature; the symptoms of diaphragmatic hernia are almost invariably greatly exaggerated in the recumbent position. Approximately 95 per cent of diaphragmatic hernias occur on the left side. The contents of these hernias vary greatly; there may be herniation of a single organ or almost all the abdominal viscera.

The symptoms of diaphragmatic hernia are extremely variable. Often the first clear clinical picture is a simulation of acute obstruction of the bowel. The diagnosis is more frequently in error than correct in these patients. They are often treated (both surgically and medically) for heart disease, peptic ulcer, cholecystitis, irritable colon, colitis or carcinoma of the esophagus for years before the true nature of the disease is determined. The proof of diaphragmatic hernia depends on x-ray visualization of abdominal viscera within the thoracic cavity.

In the present instance, correction of the severe anemia should be done prior to any attempt at surgical procedure.

DIATHERMY AND HYPERTENSIVE RETINITIS

To the Editor:—A man aged 65 became almost completely blind in early manhood when a ball struck him in the right eye. At present vision is 10/200 with an extensive central area of chorioretinitic degeneration. In November 1937 the vision of the left eye was corrected to 20/20 and no retinal abnormality was noted. Three weeks later serious loss of vision occurred. Reexamination of the left eye showed retinal hemorrhages and exudates in the macular area; vision was 20/100. Subsequent hospital examination indicated hypertensive retinitis and suggested that the macular lesions were of vascular origin associated with general arteriosclerosis. Blood pressure was 158 systolic, 80 diastolic. My own examination of palpebral peripheral vessels shows no thickening or hardness of the vessel walls. There is von Recklinghausen's disease of the skin of moderate severity. All laboratory tests and physical examination are essentially negative. He has received potassium iodide for one and one-half months with no resorption or visual improvement. Smoking and drinking have been discontinued. Is there any danger in trying physical therapy, such as short wave, on the left eye? What routine should be used in applying it? What is the prognosis for visual improvement? Have you any suggestion as to medication?

M.D., New York.

ANSWER.—Short wave diathermy has been recommended by Gutsch for the conditions described (*Transactions of the German Ophthalmologic Congress* 51:221, 1936). He used the Siemens ultratherm with glass shell electrodes placed from 1 to 3 cm. from the globe, and the current advised by the manufacturers for therapy; time from five to fifteen minutes, treatments from two to three times a week. He observed no harmful effects, but a few reports of retinal hemorrhage following such treatment are on record. It is certainly doubtful whether results could be expected by this method which would not be obtained by spontaneous absorption of hemorrhages. The use of large amounts of vitamin B as advised by Carroll in toxic amblyopia (*Arch. Ophthalm.* 18:948 [Dec.] 1937) would have no particular application in this case. It might be tried as part of the general treatment in case damage to the nerve by nutritional deficiency

might be an additional factor but without expecting too much from the method. General hygienic measures, especially rest and any other measure to control blood pressure, would offer the best chance of preventing further damage. A slight improvement of vision is sometimes observed in cases which are brought under such control. Control of the blood phosphorus content, elimination of sodium chloride from the diet and administration of ammonium chloride 1 Gm. four times a day, may be of value in controlling edema.

CORONARY THROMBOSIS IN WAR VETERAN

To the Editor:—An ex-service man aged 42 was suddenly seized with an acute coronary thrombosis. The diagnosis was verified by electrocardiography. His past history was entirely irrelevant and his family history was good. His habits were conservative. At no time since his discharge from the army has the patient been under any mental or physical strain, nor has he ever been subjected to any financial or domestic responsibilities. His occupation, barber, is anything but exacting. Since the etiologic factors ordinarily found in coronary disease seem to be absent in this individual, and in view of the rather early occurrence, is it too far fetched to assume that the ten months he spent in the front line trenches, with all the suffering and physical and nervous insults incident to modern warfare, may have been a contributing factor to the early development of this disorder? Have any studies been made or are any statistics available to show the incidence of coronary disease in war veterans? Is it possible that the present day increase in coronary artery disease may be the price that our heroes of 1918 may be paying in 1938?

M.D., New York.

ANSWER.—The question is whether a ten months period of military service in the front line trenches twenty years prior to the attack of coronary thrombosis might have been a contributing factor.

The data in the Veterans' Administration indicate a steady increase in the number of cases of coronary thrombosis for hospital treatment. In addition an increased incidence of coronary thrombosis has been found at necropsy. It must be concluded, therefore, that the increased incidence of coronary thrombosis in the ex-service population at this time is due to the aging of the veterans.

Considering all the information available with regard to the circumstances surrounding the case in question, it would be difficult to establish a causal relationship between military service twenty years ago and an acute attack of coronary thrombosis at this late date.

SUBCUTANEOUS ATROPHY FROM INSULIN

To the Editor:—A girl aged 6 years is now on her fourth year of insulin. The insulin has been given in doses varying from 3 units twice daily to 10 units three times daily, all possible regions of the body being used, and no one region used for more than a few doses in succession. Yet there have developed on the arms and legs five or six "atrophic areas," or areas of shrinking or indentation of soft tissues. The new protein zinc insulin has not been used. These areas began appearing six months ago and are increasing in size and number. Should this condition cause undue concern? Any suggestions would be appreciated.

ROBERT J. RALSTON, M.D., Holyoke, Colo.

ANSWER.—Almost invariably, areas of atrophy of subcutaneous fat due to insulin will disappear in time if injections are discontinued in the part of the body affected. Such areas are distinctly less common with protamine zinc insulin, but they may occur. This lower incidence is related probably to the fewer injections required and possibly to the neutral reaction of the material. To prevent the occurrence of new lesions, U-80 insulin, regular or protamine, is indicated, as is also care as to distribution of doses. By constant shifting of the site of injection, it should be arranged so that no one area receives insulin oftener than once in four weeks. One should remember that, in addition to the upper arms and thighs, the abdominal wall and flanks provide excellent sites for injections.

URETHROGRAPHY WITH BARIUM SULFATE,
SODIUM IODIDE

To the Editor:—Is there any danger in the injection of barium sulfate into the urethra for x-ray purposes, if the solution goes into the bladder? If so, what solution may be used for this purpose?

M.D., Nebraska.

ANSWER.—There is no important danger from absorption when barium sulfate is injected into the urethra for x-ray visualization. Under certain circumstances of obstruction of the bladder neck, if this substance should be forced back into the bladder it might possibly be the basis for the formation of bladder stone and for this reason, if for no other, its use would be contraindicated.

There is no indication for using such a substance when there are many others specially devised for this purpose. A simple

and yet useful and practical medium for urethrography is ordinary 12.5 per cent aqueous solution of sodium iodide.

Dr. Flocks of the University of Iowa has suggested the use of 10 per cent sodium iodide in jelly as an ideal medium for urethrograms and has demonstrated its efficacy on many occasions. It is now generally considered the ideal medium for this purpose.

SALT WATER THERAPY

To the Editor:—I would greatly appreciate any information relative to the use of salt water therapy in different chronic conditions.

STERLING W. OBENOUR, M.D., Zanesville, Ohio.

ANSWER.—Much has been said and written on the value of salt water baths in health and in certain diseases, both acute and chronic. There is little objective evidence, however, to the scientific critic to indicate that the presence of salt adds much to the therapeutic effectiveness of baths. It is more probable that the temperature is the effective element rather than the presence of the salt.

More optimistic reports of the value of salt water baths and sea bathing have appeared in the literature principally from the continental and English spas. If a more favorable view is desired, the following references may be consulted:

DURATION OF RETENTION OF RUBBER TUBE IN BILE DUCT

To the Editor:—How long has a rubber tube been known to remain in the bile duct? I am not referring to a T tube or drain but to a rubber tube used for the purpose of reconstructing or inside tracking operations of the biliary duct channel, such as that used in the Mayo operation in choledochoduodenostomy to maintain patency. There are several references in the literature stating that these tubes have been kept in place for as long as four years.

P. A. CONSALES, M.D., BOSTON.

ANSWER.—The longest period so far as known that a tube has remained in the bile duct following a reconstructive operation for stricture was twelve years. This occurred in the case of a foreign surgeon. The interior of the tube became encrusted with bile pigment debris, which obstructed it. It was removed at the time several visiting surgeons from the United States were in attendance.

CONTRACTED PUPILS

To the Editor:—A single woman aged 42 noticed a few months ago that the sight of her left eye was affected. She is a school teacher. January 15 her vision for the left eye was fingers at 6 feet. The vision of the right eye was 20/10, no error. The pupils of each eye are small, almost pinpoint. There was a slight reaction when exposed to light, noticeable only at the pupillary margin. The puzzling feature of this case is that the pupil of each eye will not dilate under a strong solution of atropine applied every few hours for two days. A view of the fundus is impossible. The eye with poor vision is not inflamed. Tension is normal. No watering or secretion occurs. The vision has remained the same since January 15. Complete laboratory tests, including the Wassermann test and x-ray examination of the sinuses and lungs, have been made and found to be comparatively negative. Some scars in the lungs indicate an early tuberculous involvement, which has healed. A slight cloudiness of the left antrum, possibly imaginary, prompted an opening through the nasal passage, but the antrum was found to be free from infection. One or two teeth showed some infection and have been extracted. Have you any record of any eye with normal vision and free from inflammation the iris of which does not respond to atropine?

W. R. THOMPSON, M.D., Fort Worth, Texas.

ANSWER.—The description of the eye gives no information as to what might be ascertained by a slit lamp examination. If, with the slit lamp microscope, one sees old keratic precipitates or pigment on the lens capsule, it would indicate that the pupils are small because of an old healed iridocyclitis with posterior synechiae. A thickened iris or one with sclerotic blood vessels might have a miotic pupil which does not dilate well with mydriatics even as strong as atropine. Following slit lamp examination an attempt to dilate the pupil with a subconjunctival injection of a mixture of cocaine 1 per cent, atropine 1 per cent, and 1:1,000 solution of epinephrine should be made. One may use 1 per cent suprenin bitartrate jelly twice daily. Either or both of these will sometimes dilate an iris bound down by posterior synechiae.

GASTRO-ENTERITIS AND WATER SUPPLY

To the Editor:—A city water supply was augmented by the water from a well which had been unused for several weeks. From six to eight hours after this, a large percentage of the users of the combined water were taken suddenly ill with vomiting and diarrhea. There was no fever. These symptoms lasted from a few hours to about a day. Biologic analysis a few days later showed the water from the well which had been idle to be contaminated with *Bacillus coli* and *B. aerogenes*. There was reason to think that the water might have contained extraneous inorganic material. Is it probable that the introduction of contaminated water into the supply would cause such prompt afebrile symptoms either from the organisms themselves or from possible derivative products? Is it the rule or even the rare exception that water thus contaminated would have such results? Would it not be more likely, if any symptoms were occasioned, that they would be accompanied by fever and would have a delayed onset? Your opinion together with references on this matter would be appreciated.

T. L. CHADBOURNE, M.D., Vinton, Iowa.

ANSWER.—The sudden introduction of sewage-polluted water into a pure water supply has on occasion resulted in gastro-enteritis with an incubation period of from eight to twelve hours. A number of days later typhoid or other enteric diseases of bacterial origin may appear (Jordan, E. O., and Irons, E. E.: *J. Infect. Dis.* 11:21, 1912). The etiology of the initial gastro-enteritis is obscure. Although the presence of *Bacillus coli* is suggestive of fecal contamination of the well water, it is not possible to assay the potability of a water on this basis alone. Unless the water was so heavily contaminated as to approach sewage, it is unlikely that its introduction into the city supply would result in gastro-enteritis of such a short incubation period. Contamination with heavy metals is a possibility also. Certain natural waters of the acid peaty type, for example, that have been in contact with copper pipes may give rise to gastrointestinal symptoms. In the absence of sufficient information, it is impossible to say whether or not the introduction of the well water in question bore a relation to the outbreak of gastro-enteritis.

SAFETY OF DENTAL X-RAY EXPOSURES

To the Editor:—I am using the regular type of dental x-ray machine with 10 milliamperes. What would be the maximum amount of exposure that I can give a patient at the same area with safety?

PHILIP GREENBERG, M.D., Bronx, N. Y.

ANSWER.—A dental x-ray equipment giving 10 milliamperes was tested for output in roentgens. There was a filter of the bakelite case of the box enclosing the tube as well as the layer of oil surrounding it. The measured dose was 2 roentgens per second when the focal spot of the tube was about 7 inches from the skin of the face. The average exposure for a molar is ten seconds, so the dosage would be about 20 milliampere-seconds for a molar. About half that would suffice for an incisor. The maximum safe exposure over any given skin area with the dental equipment described under the conditions named would be 200 milliampere-seconds.

STERILIZATION OF BONE PLATES

To the Editor:—What is the proper method of sterilizing beef-bone plates and screws?

J. W. McROBERTS, M.D., Sheboygan, Wis.

ANSWER.—There are only two methods: thermal and chemical. One group does not use plates but boils the pegs twenty minutes. Others put them in the autoclave for ten minutes. In the old days before chrome plated instruments were in general use there was danger of using chemicals because of corrosion; but that does not occur at present.

DIAGNOSIS OF PENILE ULCER—DUCREY VACCINE

To the Editor:—In the discussion of "Diagnosis of Penile Ulcer" (*THE JOURNAL*, July 16) reference was made to "dmelcos" and the difficulty in obtaining this European vaccine. The Ducrey vaccine for the diagnosis of chancre is available in this country and is listed by the Lederle Laboratories, Inc., among their products. For the last two years the University of Georgia School of Medicine has distributed this "vaccine" to scores of medical institutions and physicians who have manifested an interest in its diagnostic value. Chancroidal bubo pus has been shown to be inferior to the vaccine in diagnosis (Greenblatt, R. B., and Sanderson, E. S.: Diagnostic Value of the Intradermal Chancroidal Test, *Arch. Dermat. & Syph.* 26: 486 [Sept.] 1937; *Am. J. Clin. Path.* 7: 193 [March] 1937). The vaccine may be made with moderate ease in any competent laboratory by employing the technic used at the University of Georgia School of Medicine (Sanderson, E. S., and Greenblatt, R. B.: *South. M. J.* 30: 147 [Feb.] 1937). Ducrey vaccine made from strains of Ducrey bacillus of American origin has been shown to be the equal of European "dmelcos" as a diagnostic procedure (Greenblatt, R. B., and Sanderson, E. S.: *J. M. A. Georgia* 27: 218 [June] 1938).

G. LOMBARD KELLY, M.D., Augusta, Ga.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, September 3, page 963.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Examinations will be held in all centers where there is a Class A medical school and five or more candidates who wish to write the examination, Sept. 12-14. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An affiliate of the American Board of Surgery. New York, Oct. 21-22. Sec., Dr. Paul M. Wood, 745 Fifth Avenue, New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Written.* Various large cities in the country about Oct. 1. *Oral.* St. Louis, Nov. 11-12. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written* examinations will be held in various parts of the United States, Oct. 17 and Feb. 20. Application for the October examination must be received before Sept. 15 and for the February examination on or before Jan. 1. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written* examination and review of case histories of Group B applicants will be held in various cities of the United States and Canada, Nov. 5. General examination for all candidates (Groups A and B) will be given in St. Louis, June. Applications must be filed not later than sixty days prior to date of examination. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: New York, Oct. 7, and Washington, D. C., Oct. 8. Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Memphis, Tenn., January. Applications for this examination must be filed with the Secretary on or before Oct. 15. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Washington, D. C., Oct. 7-8. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: Detroit, October 26; Rochester, N. Y., November 13; and Oklahoma City, November 15. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: New York, Dec. 28-30. Sec., Dr. Walter Freeman, 1028 Connecticut Ave. N.W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: Atlantic City, N. J., Sept. 15-18. Sec., Dr. Byrl R. Kirkin, 102-110 Second Ave. S.W., Rochester, Minn.

AMERICAN BOARD OF UROLOGY: New York, Jan. 13-15. Applications must be submitted not later than Oct. 1. Sec., Dr. Gilbert J. Thomas, 1009 Nicollet Ave., Minneapolis.

District of Columbia July Report

Dr. George C. Ruhland, secretary, Commission on Licensure, reports the written examination held in Washington, July 11-12, 1938. The examination covered nine subjects and included sixty questions. An average of 75 per cent was required to pass. Twenty-four candidates were examined, all of whom passed. Eight physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
George Washington University School of Medicine.....(1935)	77.7, 84.2, (1937) 83.5, 85.2, 85.7, 85.7, 86.2, 86.5, 88.2		84.9,
Georgetown University School of Medicine.....(1936)	80, (1937) 84, 85.3, 85.3, 86		79,

Book Notices

The Radiology of Pulmonary Tuberculosis. By J. E. Bannen, M.B., Ch.B., D.M.R.E., Radiologist, Hull Corporation Hospitals and Tuberculosis Clinics. Fabrikoid. Price, \$4.50. Pp. 156, with 39 illustrations. Baltimore: William Wood & Company, 1937.

This splendid piece of work is complete in every detail and yet very brief. Bannen begins his monograph with a discussion of the technic of radiography and a brief mention of the principles of tomography and kymography. In the second chapter the author discusses from an anatomic and radiologic standpoint the normal lung with its anomalies and variations. He also discusses the topographic anatomy of the lung and the diaphragm and mediastinum as they appear in the normal roentgenogram of the chest. With this as a foundation he devotes seven chapters to the interpretation of the roentgenogram of the chest, translating the various shadows seen in terms of the underlying pathologic condition, e. g. atelectasis, emphysema, bronchiectasis, exudative lesions, caseation, fibrosis, calcifications, cavitations. He also adapts the various shadows to the pathogenesis of tuberculosis and to the pathologic physiology, and the interpretation of the chest roentgenogram after bronchography and artificial collapse therapy. One chapter is devoted to the differential diagnosis of the x-ray shadows which simulate the shadows of the various types of pulmonary tuberculosis, such as pneumonia, bronchopneumonia, Hodgkin's disease, silicosis and passive congestion of the lung due to heart disease. The illustrations are reduced negative prints of the roentgenogram of the chest, diagrammatic sketches and photographs. The only criticism is that the book is rather brief for the beginner and leaves much to the knowledge of the general practitioner. This lack is compensated for by a fine list of references after each chapter. The value of the book as a contribution to the literature lies in the fact that it stimulates the general practitioner to learn to interpret his x-ray plates, leads him to understand the importance of the roentgenogram in the diagnosis and treatment of pathologic conditions of the chest and to appreciate the importance to treatment and prognosis of serial roentgenograms at three to six month intervals. This contribution also reveals the importance of stereoscopic plates for the first roentgenogram and also the value of oblique and lateral views. However, the cardinal effect of the monograph on the general practitioner is to stimulate more frequent use of the roentgenogram in the diagnosis of chest conditions, a form of stimulus which will do much for the early diagnosis of pulmonary tuberculosis.

Die Psychiatrie im Dienste der Wehrmacht. Von Adolf Heidenhain. Mit einem Vorwort von Professor Dr. J. Lange. Boards. Price, 2.80 marks. Pp. 53. Leipzig: Georg Thieme, 1938.

From an American point of view, perhaps, treatment of psychopathology should be the most important medical function in Germany today; but the most recent literature which has come out in psychiatry and psychology has dealt largely with the improvement of the thinking processes of the German people through sterilization and what is euphemistically known as race improvement. Since the problem of restoration of German morale seems to depend on rebuilding its armed forces, it is not surprising that the present volume, which deals with psychiatry in the service of rearmament, has appeared. What

is surprising is the fact that it is only a small pamphlet, that it is not particularly scientific, that it is not deeply thought out and probably from the point of view of military surgeons and military psychiatrists is not particularly important. However, the author does acknowledge that it is only an introduction to the subject and not a complete survey. The problems of psychiatry in the army, as presented by Heidenhain, seem to be principally those which would confront the mental physician in dealing with large groups of individuals who have been torn from their homes, who are more or less segregated from females, and who are more or less unselected as to mental capacities. Feeble-mindedness is barely touched on, the implication being that it is not important to the military. Although much of it is extremely interesting, presenting the author's observations of the recent recruit called to the colors in his country, the important feature that appears in this study is the fact that mental and nervous disease is not particularly significant, either because the age of onset of these diseases is above that of the recruits or because the chief mental problem observed in the old German army of homesickness has now been done away with, as recent recruits have been brought up in various camps from early childhood and assume cantonment life to be a normal life. Alcoholism is very important but, of course, as one would expect in such a young group, it is usually of an acute form, not chronic. There is no attempt made in this book to show how mental hygiene can be used in adjusting these individuals and very little insight is shown into secondary political psychiatric problems which naturally arise in such a dominant army and navy. There is a bibliography which is not as extensive as it could be, perhaps, but it does draw on some foreign sources. This little volume will probably be more of cultural and political interest to Americans, be they physicians or not, than of any particular medical importance.

General Relief Statistics for the Fifteen-Month Period January 1936 Through March 1937. Works Progress Administration, Harry L. Hopkins, Administrator. Corrington Gill, Assistant Administrator. Emerson Ross, Director, Division of Research, Statistics and Records. Prepared under the direction of T. E. Whiting. Paper. Pp. 57. Washington, D. C.: United States Government Printing Office, 1938.

The Social Security Board became responsible for the collection and publication of general relief statistics beginning in April 1937. This bulletin covers a period of fifteen months from January 1936 through March 1937, and the data supersede the figures for these months published previously in General Relief Statistics Bulletins issued by the FERA and for a time issued jointly by this agency and the Social Security Board. The figures presented cover the number of family and single person cases and the total number of persons receiving general relief, the amount of general relief extended to cases and the total obligations incurred for relief. The term "general relief" does not include wages paid for work done under the Works Program, loans or grants made by the Farm Security Administration, aid to veterans or old age assistance, aid to dependent children or aid to the blind. The term "case" as used denotes a family or single person. The estimated number of "cases" receiving general relief in the country at large rose to a winter peak of 1,723,000 in February 1937 and in the following month declined to 1,681,000. Between March 1936 and March 1937 the number of cases declined 16.4 per cent, whereas between January 1936 and January 1937 the number of cases on general relief declined 25.1 per cent. The changes in the number of cases receiving general relief during the fifteen month period covered by this bulletin were influenced by variations in works program employment, variations in seasonal needs, changes in private employment, availability of funds, and administrative policies of state and local relief administrations; the great diversity of financial and administrative policies contributed to differences from state to state in the extent to which general relief needs were met. During February 1936 public aid in the form of old age assistance, aid to dependent children and aid to the blind under the Social Security Board was inaugurated in a number of states, and the expansion of this program in subsequent months resulted in removing a large number of persons from the general relief rolls. The effect of private employment on general relief became especially evident after February 1936. However, the employ-

ment gains in the spring and summer of 1936 were somewhat offset by the seasonal decline in the automobile and coal mining industries during the summer, although private employment gained momentum after August 1936. The longshoremen's strike on the Pacific Coast and strikes in the automobile industries in 1937 caused a temporary rise in the number of cases receiving general relief in the areas affected. In January 1936 it is estimated that about 7,211,000 persons, or 5.6 per cent of the total population of the country, received general relief. In March 1937 this number was reduced to 5,333,000, a decline of 26 per cent. The amount of general relief issued was \$47,915,000 in January 1936 and \$39,679,000 in March 1937, whereas the amount of general relief extended declined only 17.2 per cent between January 1936 and March 1937. The drop in the number of cases receiving general relief amounted to 24.1 per cent, indicating that during this period there was an increase in the average amount per case receiving general relief. The total amount extended to cases for general relief during the period January 1936 through March 1937 was \$553,453,000. It was impossible to obtain complete reports for all the states for this fifteen month period, and it was necessary therefore to prepare estimated totals. All estimates for the continental United States for this fifteen month period are therefore subject to revision on the receipt of more adequate data. The bulletin states that the estimates given are substantially correct and that any further revisions will be relatively small. A great part of this bulletin is a tabulation of the data referred to by states and by month. General and emergency relief data for the preceding three year period may be found in greater detail in the Statistical Summary of Emergency Relief Activities, published by the FERA, while figures for the period beginning with April 1937 may be obtained from publications of the Social Security Board.

O líquido cefalo-raquidiano em clinica. Pelo Oswaldo Lange, 3.^o assistente da Clínica neurológica da Faculdade de medicina da Universidade de São Paulo. Prefácio do Prof. A. de Almeida Prado. Paper. Price, 20 milreiros. Pp. 200, with 27 illustrations. São Paulo, Caxeliras & Rio de Janeiro: Companhia Melhoramentos de São Paulo, 1937.

The author discusses the physiology and anatomy of the brain and spinal cord, with a discussion on the origin of the cerebrospinal fluid. There are twelve chapters, each dealing with a clinical entity. These clinical conditions are illustrated by charts and by reproductions of photographs. The most valuable section is the one which deals with the manometric pressure and the examination of the spinal fluid in various types of spinal blockade. There is little information on the subject of cerebrospinal fluid contained in this book which is not already known in the American literature. There are occasional references to Cushing and his associates, but as a rule the references at the bottom of the page refer to foreign literature.

Food and Physical Fitness. By E. W. H. Cruickshank, M.D., D.Sc. M.R.C.P., Regius Professor of Physiology, The University of Aberdeen. Foreword by Sir John B. Orr, D.S.O., M.D., D.Sc., Director of the Rowett Institute, Aberdeen. Cloth. Price, \$2. Pp. 148. Baltimore: William Wood & Company, 1938.

This book is based on a series of public lectures on nutrition at the University of Aberdeen and it is directed to the general public. While written interestingly, it contains a few points which careful editing would eliminate or correct and thereby add to the value of the book. On page 21 reference is made to the work of "Chittenden in Boston." Boston and New Haven are related in more ways than one, but they are still distinguishable. On page 29, cheese is discussed without reference to the great differences in composition of various kinds of cheese. On page 31 appears the interesting assertion that "uric acid is not entirely a waste product; a certain amount is excreted by the kidneys, but some is reabsorbed by them in order to keep the uric acid content of the blood at its physiological level." In the chapter on minerals "Iron" appears as a heading on page 55 and again on page 60. There is further need for improvement in the headings of the chapter on vitamins and dietary deficiency diseases. On page 90 "Vitamin E" appears as a primary heading and "Vitamin Standards" as a subheading. On page 92 the unit of vitamin C is stated as "the vitamin activity of 0.05 cc. of ascorbic acid." Obviously this should be "0.05 mg." of the pure crystalline ascorbic acid. On page 93 there is a footnote to a table on the vitamin content of foods which erroneously

states that vitamins A and D are in international units and the others (vitamins B₁, C and G) in Steenbock units. There is one really important criticism and that with regard to the section on the effect of pasteurization on milk. This section now reads as though the heat treatment of milk is of questionable value which, of course, it is not. Thus the author lists six things which happen to milk when it is boiled, namely the destruction of lactic acid bacilli, the inactivation of enzymes, the loss of vitamins, the loss of part of the iodine, a slight diminution of the lime salts due to the rendering insoluble of a small amount of calcium which adheres to the side of the pan in which the milk is boiled and, finally, the denaturation of proteins so that "the casein is no longer the natural protein as found originally in the milk." Contrast this type of statement, which is intended for the general public, with two statements issued by the Council on Foods relative to the pasteurization of milk: "The public should demand pasteurized milk for drinking and the use of pasteurized milk in milk products. The dairy trade should universally adopt pasteurization in the interest of public health." It has also been stated that "in the opinion of the Council, all milk used for infant feeding should be boiled." There should be no confusing of the issue in the public's mind and, in this respect, the book falls short of its purpose.

Fearfully and Wonderfully Made: The Human Organism in the Light of Modern Science. By Renée von Eulenburg-Wiener. Cloth. Price, \$3.50. Pp. 472, with 18 illustrations. New York: Macmillan Company, 1938.

This book contains an extraordinary amount of material, fairly well digested and reasonably accurate. It is not a book for the serious student but should be valuable as a popular presentation. It attempts to present factual detail about human anatomy and physiology in a manner understandable to the layman. In this it is probably successful. However, the author rides certain hobbies, such as the importance of optical isomerism and the philosophical implications of the quantum theory, to an absurd degree. For this defect the publishers are perhaps as much to blame as the author, in not having obtained competent criticism. It will be worth while to list a random sample of errors in fact. Page 4: "The chemist is unable to form [organic] compounds in such a manner that they will exhibit the property of optical rotation." Page 70: "Chlorine is more or less equally distributed between the cells and the surrounding fluid . . . of the body." As a matter of fact it is more than likely that most body cells contain no chloride whatever. Page 85: "The greatest amount of work done by the heart is expended in overcoming resistance in the circulatory system; only a small amount of the total energy utilized determines the rate of the blood flow." The second clause is incorrect if the first is true, as it is. Page 88: "The elasticity of the arterial vessels is of great importance. It is partly due to this elasticity that the pressure of the blood decreases as the blood enters smaller and smaller vessels. Decreased elasticity of the arterial walls is one of the factors which brings about increased blood pressure." The first sentence is obviously true, the second is absolutely incorrect, and the third is open to great argument. These examples are among many more in the same category.

With regard to the more definitely philosophical aspects of the work it can be said that the general principle is the application of modern non-materialistic physical ideology to biology. There is a good deal of loose reference to such ideas as for example that an increase in entropy represents senescence and death, and that "living substance like all matter is ultimately resolvable into sources of radiant energy and therefore may be considered but another form of radiant energy." The latter assertion is objectionable if for no other reason than because it suggests "another form" of energy in living from those in nonliving systems. The author (p. 446) makes the gratuitous assertion that "biology holding to the materialistic explanation of life has to restrict itself to isolated processes in the elucidation of living phenomena." If this were true, of course, the author would be right in her further remarks about its inadequacy. But such a restriction is unnecessary and no mechanist would allow it. The author has set up her own inadequate straw man to knock down. Another statement requiring con-

troversion is that "the uncertainty principle [of Heisenberg] rules in the biological sciences to a still greater extent [than in the physical]." There is not the slightest evidence that this principle is of any special consequence in biologic activity. Certain noted physicists have indicated in popular books that they imagine the "uncertainty principle" might solve the enigma of the freedom of the will and other things physicists in general know nothing about, but it hardly seems appropriate to attach positive significance to a physicist's biologic imaginings.

Youth Tell Their Story. By Howard M. Bell. A Study of the Conditions and Attitudes of Young People in Maryland Between the Ages of 16 and 24. Conducted for the American Youth Commission. Paper. Price, \$1.50. Pp. 273, with illustrations. Washington, D. C.: American Council on Education, 1938.

Once again the obvious is proved by an elaborate investigation. The American Youth Commission and the American Council on Education have discovered and assembled detailed evidence to prove that in the lower income classes the children must help support the family, that they receive less medical and dental care and that they live in houses with fewer conveniences. The unemployed youth desire a home and family, but marriage is delayed. They left school younger than those in the higher income classes, and 40 per cent of those that left did so for economic reasons, while they still wish more education. They get poorer jobs. They do not attend church. They are looking to the government for help but want work rather than relief. Only 55 per cent of them are sufficiently interested in politics to vote. All this is stated statistically and illustrated by diagrams on the basis of questionnaires circulated in the city of Baltimore and held to be representative of the United States.

The Diet Book for Doctor, Patient and Housewife with Specimen Menus for One Week and Recipes. By Marguerite Requa Rea (Mrs. Alec L. Rea). With a foreword by Sir James Purves-Stewart, K.C.M.G., C.B., M.D., Physician to Westminster Hospital. Third edition. Cloth. Price, \$2.25. Pp. 255. New York & London: Oxford University Press, 1937.

This book has been prepared primarily for the housewife and cook to enable them more adequately to prepare foods for the sick. In the present edition, additional dietaries suitable for maladies not contained in the previous editions have been included. Among these are the ketogenic diet and diets for nephritis. The first portion of the book outlines the meals to be employed in various conditions, while the second section is devoted to recipes and tables.

The value of the book for those in this country is limited by the inclusion in the meals of certain products not available. Trade preparations are liberally employed. Even with these limitations, the material will find a field of usefulness for those who must prepare food for the sick and convalescent. The physician may also find information of value to aid him in the planning of certain dietaries.

Medical Service in Industry and Workmen's Compensation Laws. Prepared by M. N. Newquist, A.B., B.Sc., M.D. Paper. Pp. 70, with 11 illustrations. Chicago: American College of Surgeons, 1938.

The natural interest of the American College of Surgeons in the treatment of industrial injuries has led to a study of industrial medicine, the organization and functions of industrial medical and surgical service, and workmen's compensation, all of which are covered in this report. The position is consistently maintained that such service should be confined to plant conditions and that, "if for no other reason than a sense of fair competition, industry should go no further in the actual treatment of non industrial injuries and illnesses than to give reasonable first aid and advice to those on duty." This leaves a wide and valuable field for medical activity in plant sanitation, physical examinations, safety measures and, in short, guarding against all conditions within the plant that may prove harmful to health. Statistical studies of the extent of medical service in industry and its effect on accidents and disease are presented. There is an excellent summary of the history and essential features of workmen's compensation laws and insurance systems in industry. The report is a compact presentation of information of value to any one interested in industrial medicine.

Baby's Point of View: The Psychology of Early Babyhood. By E. Joyce Partridge, F.R.C.S., L.R.C.P. Cloth. Price, \$1. Pp. 94. New York: Oxford University Press, 1937.

Here is an attempt to explain behavior problems in childhood and neurotic conditions of adulthood by showing that the baby has a good deal of understanding at the early age of 2 to 3 weeks and that any drastic upheaval in its life at so early an age may be the basis for neurotic tendencies later in life. It is recommended that the mothers use their maternal instinct and intuition in caring for the infant rather than the rules of inflexible regularity of feeding and sleeping. In other words, "mothering" is advocated to prevent the child from becoming hysterical because of fear and crying. Breast feeding and the closeness of the mother, it is stated, keep the baby from feeling unsafe. This book with its new point of view will be found interesting to the physician as well as to the mother and nurse.

Intercity Differences in Costs of Living in March, 1935, 59 Cities. By Margaret Loomis Stecker. Works Progress Administration, Division of Social Research, Research Monograph XII. Paper. Pp. 216. Washington, D. C.: United States Government Printing Office, 1937.

The purpose of this study was to determine the costs of living in fifty-nine separate cities, first at a "basic maintenance level" and second at an "emergency level." The costs of living are determined by the retail prices of the goods and services essential to maintaining these levels. The family was assumed to consist of the father, mother, a boy aged 13 and a girl aged 8, and the figures to apply to March 1935. At that time it was determined that the average expenditure required in the fifty-nine cities to procure the "maintenance level" would be \$1,261 and the "emergency level" \$903. As might be expected, the lowest cost was found in the South Central states, but the closest correlation was in the increase of cost according to the size of the cities. The average cost for medical care was \$52.32 a year. This medical care is made up not only of the personal services of physicians, dentists, nurses and hospitals but also of a list of drugs and appliances purchased by the patients. There might easily be some question as to these drugs and appliances.

The American Illustrated Medical Dictionary: A Complete Dictionary of the Terms Used in Medicine, Surgery, Dentistry, Pharmacy, Chemistry, Nursing, Veterinary Science, Biology, Medical Biography, Etc., with the Pronunciation, Derivation, and Definition. By W. A. Newman Dorland, A.M., M.D., F.A.C.S., Lieut.-Colonel, M. R. C., U. S. Army. With the collaboration of E. C. L. Miller, M.D. Eighteenth edition. Fabrikoid. Price, \$7; Thumb indexed, \$7.50. Pp. 1,607, with 942 illustrations. Philadelphia & London: W. B. Saunders Company, 1938.

New terms appear in medical literature these days with astonishing rapidity. In the present edition of this well known dictionary, 3,000 new words have been defined. As a result the text is increased by more than sixty pages. The largest number of revisions and additions appear in the fields of endocrinology, immunology, pathology and biopsychology. More than 100 new tests are described. In the development of this dictionary, the editorial department of the American Medical Association cooperates, bringing the choice of terms into accord with the style book of the American Medical Association Press. An interesting feature of the dictionary is the portraits of distinguished investigators, together with brief biographic notes.

Major Endocrine Disorders. By S. Lery Simpson, M.A., M.D., M.R.C.P., Physician, Wilkesden General Hospital, London. Foreword by Sir Walter Langdon-Brown, M.A., M.D., F.R.C.P. Cloth. Price, 10s. 6d. Pp. 181. With 21 illustrations. London: John Bale Medical Publications Ltd., 1938.

Practitioners of medicine should welcome this authoritatively written, terse and practical summary of endocrinology. It is a precise survey of modern endocrinology that will be invaluable for purposes of orientation. While the author makes no pretense of writing a complete textbook on the subject, he has succeeded in presenting an unusual amount of well correlated data in a most lucid manner. Useless and confusing theoretical detail has been omitted from the book and the work reflects the author's rich practical and scientific background. The major endocrine syndromes of the thyroid, parathyroid, pituitary, adrenals, gonads and pancreas are discussed with masterly brevity. The work merits a place in the library of every practicing physician.

A Prairie Doctor of the Eighties: Some Personal Recollections and Some Early Medical and Social History of a Prairie State. By Francis A. Long, M.D. With two chapters on "The Prairie Doctor's Wife." By Maggie E. Long. Cloth. Price, \$2.75. Pp. 223, with 34 illustrations. Norfolk, Nebraska: Huse Publishing Company, 1937.

Here Dr. Francis A. Long, for many years editor of the *Nebraska State Medical Journal*, presents the story of his career in medicine, which includes as well the early days of development of the state of Nebraska. The work is a straightforward account with little literary elaboration but one which is certain to be of interest to every one who knew of Dr. Long and his work in Nebraska. Two additional chapters by Mrs. Long reveal the attitudes and interests of the doctor's wife.

The Psychology of Speech. By Jon Elsenon. Cloth. Price, \$2.25. Pp. 280, with 5 illustrations. New York: F. S. Crofts & Co., 1938.

After an introduction which considers the nature and origin of speech, its psychology and development, the author concerns himself with deviations in speech resulting from disorders in personality and, finally, with the speaker-audience relationship. The work seems to be based largely on earlier rather than more modern psychology. It presents nevertheless a concise consideration of that element of human conduct which most certainly distinguishes man from the animal.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Failure to Discover Fracture of Hip.—The plaintiffs, husband and wife, were in an automobile accident near Springfield, Ill., Aug. 9, 1933, and the wife was severely injured. She was taken to a hospital at Springfield and the defendant physicians were called to attend her. They found the patient in an unconscious condition and their examination disclosed a skull fracture extending from the frontal bone almost to the base of the skull. The patient remained unconscious for four or five days and her head injury was of such a serious nature that her life was despaired of. She remained in the hospital for about a month, during which time she gave many indications that she was suffering pain in her right hip but apparently no examination of the hip was made. On September 7 she was returned to her home in Kansas City by ambulance and by train, at which time the defendants' connection with the case terminated. Subsequently another physician observed that the wife's right leg was shorter than her left and a roentgenogram disclosed an unimpacted fracture of the neck of the right femur. A Whitman reconstruction operation was successfully performed but the right leg remained permanently short. The plaintiffs then sued the defendants, alleging malpractice. At the conclusion of the plaintiffs' evidence, the United States district court for the southern district of Illinois, southern division, directed the jury to return a verdict for the defendants and judgment was entered thereon. The plaintiffs then appealed to the United States circuit court of appeals, seventh circuit.

The district court directed the verdict for the defendants on the theory that the first duty of the physicians was to save the patient's life, if possible, and that even though they might have been negligent in not discovering the condition of the hip, yet they could not be held for damages unless the evidence showed that they could have safely examined and cared for the injured hip without endangering her life while she was undergoing treatment for the serious condition of her head. With this theory, the circuit court of appeals found itself in disagreement. The error in the theory was that it placed on the plaintiffs the burden, in the first instance, of proving that the patient was in a fit condition to have her hip examined and cared for without endangering her life. This placed on the plaintiffs a greater burden than the law warrants. Conceding that a prima facie

case of negligence had been established by the plaintiffs, the burden was on the physicians, if they desired to avail themselves of that defense, to prove that the patient's condition was such that examination or treatment of her hip would have endangered her life. Aside from the injury to the patient's head there was no doubt that the plaintiffs established a prima facie case of negligence, with proximately resulting damages. It may be conceded, the court said, that the head injury prevented an examination and treatment of the hip sooner than five days after the injury, for the patient was unconscious during that time. The record disclosed, however, that the patient was in a condition to undergo an examination of her hip when she regained consciousness.

The physicians owed the patient the duty of making such examination and giving her such treatment as her physical condition and the skill of their profession in that community warranted. They did nothing so far as the injury to her hip was concerned in the way either of curative or of palliative measures. It was fairly inferable from the record, the court said, that where there is a fracture of the femur, which is not impacted, there should be an apposition of the broken ends of the bone as soon as possible, if by so doing the patient's life is not endangered. That injury proximately resulted to the patient from the physicians' negligence seemed to the court to be clear. The judgment of the district court was therefore reversed, and the cause remanded with instructions to grant a new trial.—*Weintraub v. Rosen*, 93 F. (2d) 544.

Workmen's Compensation Acts: "Any and All Occupational Diseases" Construed.—The claimant sold tickets in a booth in the street outside the lobby of a moving picture theater. This booth was heated by an electric heater which the claimant could turn on or off as she wished. The alternate heat and cold to which she was subjected, she claimed, caused blotches to appear on her legs and caused her feet to become numb and weak. She complained about this condition to her employer and he sent her to a physician. On the way to the physician's office she fell and fractured her left ankle, the fall being attributed to the weakness of her feet. The industrial board awarded compensation, finding that her injuries were accidental injuries that arose out of and in the course of her employment and that the disease from which she suffered was an occupational disease compensable under the workmen's compensation act. The supreme court, appellate division, New York, affirmed the award (297 N. Y. S. 960) and the employer and its insurance carrier appealed to the Court of Appeals of New York.

The workmen's compensation act of New York includes as accidents certain named occupational diseases and then follows with a clause providing compensation for "any and all occupational diseases." It was conceded that the claimant was not suffering from any occupational disease specifically named in the act. She claimed, however, that her condition was included in the general language "any and all occupational diseases." But, said the court, the wording of the act clearly indicates that only "occupational diseases" are compensable, not all diseases contracted during the course of employment. The act does not define the term "occupational diseases," but it indicates more clearly than by definition what is meant by enumerating certain diseases, linking each with the process used by the employee by which the disease is caused, such as lead poisoning contracted in a process involving the use of or direct contact with lead. Every such disease is thereby required to be actually caused in the course of the employment and from the particular work the employee is performing. Certain sections of the act refer to occupational diseases as those due to the nature of the employment and contracted therein and expressly limit compensation to those diseases. Thus an occupational disease is one which results from the nature of the employment, and by nature is meant not those conditions brought about by the failure of the employer to furnish a safe place to work but conditions to which all employees of a class are subject and which produce the disease as a natural incident of a particular occupation and attach to that occupation a hazard which distinguishes it from the usual run of occupations. Compensation is restricted, there-

fore, to disease resulting from the ordinary and generally recognized risks incident to a particular employment and usually from working therein over a somewhat extended period. Such a disease is not the equivalent of a disease resulting from the general risks and hazards common to every individual regardless of the employment in which he is engaged.

In the present case the claimant handled cash and theater tickets and it was obvious to the court that this work in and of itself could not have caused the leg injury or disease. The disease which befell her, therefore, was caused not by the nature of her employment but by the failure of her employer to furnish her with a proper and safe place in which to work. There being no evidence whatever to sustain the finding that the claimant contracted an occupational disease in the course of her employment, the court concluded that the award could not be sustained on that ground.

The court, however, thought that the award could be sustained on the ground of accidental injury arising out of and in the course of employment. The fall occurred while the claimant, pursuant to the directions of her employer, was on her way to the physician. The fall was the result of weakness of the claimant's feet which was caused, not by an internal disorder, disease or illness having no connection with her employment, but by the conditions of her employment. The order awarding compensation was therefore affirmed.—*Goldberg v. 954 Marcy Corporation (N. Y.), 12 N. E. (2d) 311.*

Accident Insurance: Diabetes, and Death from Septicemia Following a Burn.—The defendant promised to pay the plaintiff, as beneficiary, a certain amount if the insured lost his life as the result of bodily injuries "caused directly and independently of all other causes by violent and accidental means." Among the risks excluded was death "caused wholly or partly, directly or indirectly, by disease or bodily or mental infirmity or medical or surgical treatment therefore." The insured had an ingrown toenail which was partly removed by a chiropodist. In an effort to heal the toe, the insured exposed his foot to the rays of a heat lamp, which he had been in the habit of using for therapeutic purposes. On this occasion he fell asleep and the exposure continued for a much longer time than intended, causing a severe burn on the instep. A blister developed, which subsequently broke, resulting in an open and visible wound, and septic infection set in. The leg was amputated, but the insured died of streptococcic septicemia. For three years prior to his death, the insured had suffered from diabetes mellitus. The insurance company repudiated liability on the ground that the death of the insured, if not due solely to the diabetes, was at least caused primarily by it and not by accidental injury independently of all other causes. The trial court gave judgment for the plaintiff, and the company appealed to the Supreme Court of Pennsylvania.

The trial court found as facts that the diabetes of the insured was kept under control by diet and insulin and that it did not render him more liable to a burn or to infection, nor did it in any way interfere with their treatment. Had the death resulted from the combination of the injury and the diabetes, said the Supreme Court, then, even though the injury were the proximate and the diabetes merely the remote cause, there would be no liability under the policy. In view, however, of the trial court's findings that the diabetes in no way contributed to the death of the insured and that he probably would have died of the injury alone, this defense was not available to the company. There was no merit, the court continued, in the defendant's contention that the death was not caused by "violent and accidental means." The term "violent" signifies merely that a physical force, however slight, is efficient in producing a harmful result. Here the impact of the heat rays blistered and ultimately broke the tissues of the foot. In addition to being "violent," the means were also "accidental." A means is not accidental when employed intentionally, even though it produces an unintended result. But if, in the act which precedes the injury, something unforeseen, unexpected, unusual occurs, which produces the injury, the injury has resulted through accidental means. Here the means were employed intentionally only up to the time when the insured fell asleep. He did not compose himself to sleep; the falling asleep was an accident. Thereafter, the

exposure of his foot to the heat was unintentional and involuntary and the means which produced the injury thus became "accidental."

The clause of the policy excluding liability for injury caused by medical treatment for bodily infirmity did not relieve the company from liability, the court continued. While the application of the rays undoubtedly was for therapeutic purposes and therefore constituted "medical treatment," it was not for "bodily infirmity." The latter term in insurance policies, the court pointed out, has uniformly been construed to mean a condition of a settled and substantial character materially impairing the bodily processes, and not to cover minor physical defects and ailments which are frequent incidents of life, speedily forgotten, and not affecting the general soundness and healthfulness of the system. Even a dormant duodenal ulcer has been held not to be a disease or bodily infirmity within the meaning of those terms in a policy. *Silverstein v. Metropolitan Life Insurance Co.*, 254 N. Y. 81, 171 N. E. 914. The same has been ruled in regard to burns about the ankles, leaving scar tissue, *McClure v. World Ins. Co.*, 126 Neb. 676, 254 N. W. 393; and to intestinal adhesions resulting from a herniotomy. *Druhl v. Equitable Life Assurance Society*, 56 N. D. 517, 218 N. W. 220, 60 A. L. R. 962. An ingrown toenail, said the court in this case, no more constitutes "bodily infirmity" than would an impacted tooth. The judgment of the trial court for the plaintiff was affirmed.—*Arnstien v. Metropolitan Life Ins. Co. (Pa.)*, 196 A. 491.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

16: 1-132 (July) 1938

Dissecting Aneurysm: Study of Six Recent Cases. M. Hamburger Jr. and E. B. Ferris Jr., Cincinnati.—p. 1.
Vectorcardiogram. F. N. Wilson and F. D. Johnston, Ann Arbor, Mich.—p. 14.

Measurement of Circulation Times and Agents Used in Their Determination. S. Daer and B. G. Slipakoff, Philadelphia.—p. 29.

Calcereous Aortic Valve Stenosis, with Particular Reference to Its Etiology. G. Lesnick and M. J. Schlesinger, Boston.—p. 43.

The Lag-Screen Belt Electrocardiogram. G. Asher and F. Hoecker, Kansas City, Mo.—p. 51.

Observations on Passive Vascular Exercise and Other Forms of Treatment of Peripheral Vascular Disease. W. B. Kountz and J. R. Smith, St. Louis.—p. 55.

Blood Pressure Response to Epinephrine Administered Intravenously to Subjects with Normal Blood Pressure and to Patients with Essential Hypertension. T. J. Fatherree and E. A. Hines Jr., Rochester, Minn.—p. 66.

Stethograph. M. L. Lockhart, Ossining, N. Y.—p. 72.

*Heart Sounds in Normal Children. Margaret Harper McKee, Irvington, N. Y.—p. 79.

*Heart Sounds and Murmurs in Children with Rheumatic Heart Disease. Margaret Harper McKee, Irvington, N. Y.—p. 88.

Heart Sounds in Normal Children.—In order to establish normal standards, McKee made stethographic records of the hearts of 105 apparently healthy school children. Four distinct sounds invariably accompanied each heart beat, namely the first, the second, the "physiologic" third and a supposedly auricular sound, which preceded the first. The last two were low in pitch and usually of little intensity and therefore are generally inaudible. The first or second sounds, or both, are frequently split. Sinus arrhythmia was always present. The differences in the intersphygmic intervals depend on the time elapsing between the third sound and the following auricular sound. The intensities of the various sounds depend on where the microphone is placed and vary greatly with changes in the cardiac rate. At the apex a moderately low-pitched, usually faint systolic murmur was present in all instances, which suggests that too much significance should not be attached to such murmurs when they are barely audible with the stethoscope. The investigation indicates that splitting of the first or second heart sound and the presence of a third sound have no pathologic significance.

Murmurs in Rheumatic Heart Disease.—McKee analyzed the stethograms of 130 children between the ages of 7 and 16 years, all of whom had unequivocal histories of polyarthritis, chorea or carditis of a rheumatic type. Stethograms of children with quiescent rheumatic heart disease show the same degree of sinus arrhythmia as those of normal children. In carditis this arrhythmia may disappear. Gallop rhythm may be due, at least in some cases, to tachycardia, accentuation of the third heart sound, and lessening of the intensity of the first heart sound. Of 119 children with organic heart disease 19 per cent had abnormally loud second sounds at the pulmonic area. Otherwise the heart sounds were not outside the normal range. The apical systolic murmurs which were present in cases of mild cardiac damage appeared similar to those found in normal records except for increased intensity. With more advanced cardiac disease these murmurs became slightly higher pitched. The louder, longer apical diastolic murmurs occur in cases in which the cardiac disease is relatively severe. However, when the disease is not so far advanced the short, early, faint diastolic murmur may come and go from time to time during periods when the disease is apparently inactive. Stethograms of these children show sometimes a murmur and sometimes a third heart sound. The murmur may even come and go with respiration. There are all gradations from a simple clearcut third heart

sound to an obvious long diastolic rumble. The term murmur has been used to designate any series of waves composed of more than three vibrations. Inconstant, faint, early diastolic murmurs may be due to slight relative stenosis of the mitral valve caused by cardiectasis without enlargement of the mitral orifice.

Origin of Emotional Factors in Normal Pregnant Women. J. C. Hirst and Flora Strouse, Philadelphia.—p. 95.

Pneumococcal Meningitis with Recovery: Report of Three Cases. W. B. Allan, S. Mayer Jr. and R. Williams, Baltimore.—p. 99.

Continued Use of Protamine Zinc Insulin.—Ralli and her associates discuss twenty patients with severe diabetes mellitus who were continuously on protamine zinc insulin for from one to eight months or more. At the end of this time protamine zinc insulin was discontinued because it was impossible to prevent a significant degree of glycosuria. All the patients had previously been under observation and treatment for an equal or longer period of time on soluble insulin. It was impossible to transfer successfully four of the patients to protamine zinc insulin and it was discontinued at the end of from one to two months. Of the remaining sixteen, after eight months or more of this therapy it was found necessary to return seven of the patients to soluble insulin because of the occurrence of alternating periods of uncontrolled glycosuria and insulin shock. Of the remaining eleven, eight have required soluble insulin as well as protamine zinc insulin in order to control the diabetes. In three patients the diabetes was adequately controlled on protamine zinc insulin alone. It is believed that beneficial effects followed the use of protamine zinc insulin in only these three patients. One additional patient, a 15 year old girl, has been treated successfully with protamine zinc insulin alone for a period of seven months, making a total of four patients with severe diabetes successfully treated with protamine zinc insulin. Three of the successfully treated patients were found to have low basal metabolic rates. It may be that lowered thyroid activity would tend to render these patients more sensitive to the action of insulin. If this were the case, it would naturally follow that a more slowly absorbed insulin would be more effective and that less of it would be required to control the glycosuria. Possibly this may be one of the reasons for the successful response of some patients to protamine zinc insulin.

Picrotoxin as Antidote for Barbiturates.—Rovenstine presents four case reports as examples of the clinical effectiveness of picrotoxin as an antidote for barbiturates. The cases

reported are those in which the derivative of the drug and the amount (from 4.9 to 32.5 Gm.) taken could be established with reasonable accuracy. Three patients recovered. The patient who did not recover had taken 32.5 Gm. of sodium barbital. This is usually regarded as hopelessly fatal. The experience with these patients suggests that, in human beings, results with picrotoxin in barbiturate poisoning may be anticipated which are identical with those found by Tatum and his co-workers in laboratory animals. In addition to slow intravenous infusion of picrotoxin, active, close supervision is essential. Frequent changes in position, maintenance of body temperature, support of circulation and nutrition with intravenous fluids, frequent gastric lavage and feeding, frequent catheterization, diuretics, blood transfusion, oxygen therapy and the use of an endotracheal airway and frequent cleansing of the trachea by suction through the airway are indicated and their importance is not surpassed by the use of picrotoxin.

Tuberculosis of Intestine.—Charr and Cohen determined the incidence of intestinal tuberculosis in forty-two cases of tuberculous anthracosilicosis and in seventy-five cases of non-anthracosilicotic pulmonary tuberculosis that came to necropsy. Intestinal tuberculosis was present in eight of forty-two cases of anthracosilicosis. Of the seventy-five cases of non-anthracosilicotic pulmonary tuberculosis, intestinal tuberculosis was present in thirty-eight. Tuberculosis of the intestine, when it occurs in the presence of anthracosilicosis, is most frequently found in early or moderately advanced anthracosilicosis. In this stage the incidence of intestinal involvement is practically the same as in non-anthracosilicotic pulmonary tuberculosis. In the presence of far advanced anthracosilicosis intestinal tuberculosis is uncommon; only 7 per cent of twenty-eight cases showed intestinal tuberculosis. This relative infrequency of intestinal tuberculosis appears to be due to the extensive fibrosis of the lungs and the chronicity of the pulmonary tuberculosis usually present in these patients. A combination of these two conditions apparently tends to prevent the spread of tuberculous infection to other parts of the body. The incidence of intestinal tuberculosis was greater among persons less than 30 years of age in both the anthracosilicotic and the non-anthracosilicotic group. In the majority of cases of intestinal tuberculosis in anthracosilicosis there were no symptoms referable to the gastrointestinal tract. The vague abdominal discomfort frequently complained of by anthracosilicotic patients may well be due to chronic passive congestion of the gastrointestinal tract secondary to gradual myocardial failure.

Carotid Sinus Denervation in Man.—Capps and de Takáts studied the vascular reflexes of two patients on whom bilateral carotid sinus denervation was performed eight and one-half and seventeen months previously. From the results they conclude that no permanent hypertension or tachycardia resulted from bilateral carotid sinus denervation. Furthermore, at the time of examination there was no evidence of increased sympathetic activity or increased lability of the blood pressure and pulse as might be demonstrated by exercise. However, there was a definite postural hypotension. The possibility that a similar mechanism, namely loss of sensitivity of the carotid sinuses to normal physiologic stimuli, may account for the observations in certain cases of idiopathic postural hypotension is pointed out.

Lowered Resistance in Diabetes Mellitus.—Marble and his associates performed twenty-five tests on twenty-three non-diabetic persons and twenty-seven tests on twenty-seven diabetic patients in order to discover the difference, if any, in the inhibitory action and phagocytic power of the bloods on beta hemolytic streptococci. The results are of an essentially negative character in that they show no significant difference between the bactericidal, bacteriostatic or phagocytic power of diabetic as compared with normal blood. Approximately the same variation of bactericidal or phagocytic power was found among the group of diabetic patients, regardless of duration, severity or state of control of the diabetes, as among the group of normal individuals selected at random. This variation is without doubt partly dependent on former chance contacts, chiefly during infections, between the persons concerned, diabetic or nondiabetic, and the specific (or to a less extent, related) bacterial strains used. Among other factors, aside from the possible influence of diabetes itself, is the variable capacity of individuals to respond to antigenic contacts. Diabetic patients who successfully combat past infections thereby develop specific immunity to roughly the same extent as do nondiabetic controls. It seems likely that the commonly occurring malnutrition, dehydration and acidosis of the poorly controlled diabetic per-

son may contribute to poor resistance in a manner which is not reflected in the type of study reported. Perhaps also one should consider more specifically the functional integrity of the fixed tissue cells, i. e. the mononuclear cells of the reticulo-endothelial system. The possibility exists that, in the uncontrolled diabetic patient the hypercholesteremia which is present not infrequently may be associated with a "blockade" of the reticulo-endothelial system with consequent lowering of its efficiency.

Cyanosis in Patients Receiving Sulfanilamide.—During the past year Chesley encountered eight patients in whom cyanosis developed following treatment with sulfanilamide. No significant difference was found between the calculated and the measured carbon monoxide capacities. This precludes the existence of more than minimal amounts of sulfhemoglobinemia or methemoglobinemia in these patients, all of whom had cyanosis. Experiments were carried out with methemoglobin and sulfhemoglobin to determine whether sulfanilamide would enhance the carbon monoxide capacity. Sulfanilamide had no effect on the carbon monoxide capacity of either methemoglobin or sulfhemoglobin. The frequent reactions to sulfanilamide such as headache, nausea, malaise, vertigo, lassitude, tinnitus, accelerated pulse and respiration and loss of alkali in the urine constitute the syndrome of "mountain sickness," which is caused by anoxia. If the drug does have this effect, perhaps the customary use of sodium bicarbonate with sulfanilamide is not wholly desirable. The excretion of alkali with the fall in the combining power of the blood carbon dioxide would appear to be a compensatory response to the loss of carbon dioxide blown off during the accelerated respiration. Sulfanilamide has been recommended in treating pneumonia. In pneumonia, anoxia is often already a serious complication. The fact that Marshall and Walz with seven cases, Mull and Smith in one case and the author with eight cases have not found sulfhemoglobinemia or methemoglobinemia in high enough concentration to cause noticeable cyanosis casts serious doubt on the prevalent idea that cyanosis following sulfanilamide is usually attributable to these hemoglobin derivatives. This is not to deny that in some cases the cyanosis may be so caused. Discombe did find considerable sulfhemoglobinemia in six of seven cases. He attributed this to the concurrent use of magnesium sulfate, which presumably causes an enterogenous sulfhemoglobinemia perhaps catalyzed by sulfanilamide. Paton and Eaton found four of nineteen patients to have a methemoglobinemia, which was proved spectroscopically. From this it is concluded that before cyanosis in a given case is attributed to sulfhemoglobinemia or methemoglobinemia these pigments must be identified and shown to be present in such concentration as would give the observed degree of cyanosis.

Immunization of Respiratory Tract.—Walsh and Cannon carried out experiments which demonstrate that following active or passive general immunization antibodies tend to be distributed rather uniformly through the tissues and that the ratio of tissue antibody to serum antibody is, on the average, between 1:10 and 1:15. The antibody titer of the tissues of the respiratory tract (nasal mucosa and lungs) following active regional vaccination is consistently higher than that of the other tissues tested, and the tissue antibody to serum antibody ratio of the nasal mucosa and of the lungs is, on an average, about 1:5. The method of extraction of the tissues has been improved and this has eliminated the possibility of nonspecific flocculins or

group agglutinins confusing the results, particularly in the lower dilutions. Several explanations for the consistently higher tissue antibody to serum antibody ratio of the regionally immunized tissues are possible. It is suggested that the probable explanation for the observations is that antibodies are formed locally in the regionally stimulated tissues and diffuse from them into the general circulation. Whether local formation or local concentration of antibody is the true explanation, the important fact remains that the ratio of tissue antibodies to serum antibodies is higher in tissues stimulated by regional vaccination than by either active or passive general immunization. Regional vaccination would seem therefore the preferable method for elevating the level of resistance of tissues at the port of entry to the body.

Tularemia.—Melchert reports three cases of tularemia, evidently contracted from fish that were caught in a fish trap in which a rabbit was placed as bait. All three patients were given two intravenous injections of 15 cc. each of antitularemic serum on successive days without any reaction. Two of the three patients definitely improved, one in twenty-four hours, the other in forty-eight hours after administration. The third patient seemed to be benefited only slightly. The improvement in the two instances seemed to be too prompt to have been a coincidence. The only conclusion that can be drawn is that the administration of antitularemic serum should be worth trying in other cases.

Thyroxine in Otosclerosis.—Goldstein has used one sixty-fourth grain (0.001 Gm.) of thyroxine in forty-two instances of otosclerosis in young persons, following the technic of Gray. The tablet of thyroxine placed on a watch glass is dissolved in four drops of warm sterile distilled water and is injected through the drum membrane directly into the cavity of the middle ear so that it may be in contact with the promontory and oval window. The patient's head is inclined to a completely lateral position for the ear to be anesthetized with from 15 to 20 drops of aniline oil-cocaine solution. The solution is dropped to the fundus of the canal and is allowed to remain there for five minutes, when it is carefully swabbed out. The insertion of the

hypodermic needle for injecting the thyroxine is at the point half way between the tip of the malleus handle and the posterior rim of the annulus tympanicus. Immediately after the injection, with the patient in an erect position and with his head thrown well backward, the patient is directed to keep the mouth open wide for three minutes, thus preventing part of the injected fluid from escaping down the eustachian tube. Following the injection, the patient is instructed to remain quiet for from twenty to thirty minutes and is further cautioned not to be too active for the rest of the day. The thyroxine treatment consists of four consecutive injections made alternately in the right and the left ear at intervals of one week. The selection of patients who may be best qualified to receive such treatment is based largely on one's ability to make a diagnosis of clinical otosclerosis. Patients more than 30 years of age usually are less satisfactory subjects for the treatment, either because of their age or because of the long duration and progressive character of their defective hearing. Of the forty-two patients subjected to thyroxine treatment, twenty-three have shown definite improvement in hearing capacity and in some cases cessation or reduction of tinnitus and a general clarification in the perception of speech, and ten show slight improvement by comparison of audiograms before and after injection; but this was not stabilized in the final audiograms six months or more later. In nine no improvement was noted following treatment. In no case was there any decrease in hearing following these injections.

Tolerance to and Toxicity of Insulin.—In an attempt to determine the tolerance to and toxicity of insulin after cautious trials with ascending doses of insulin in several patients in the Psychiatric Institute, Allen gave a strong, young diabetic patient subcutaneous injections of 750 and 1,000 units of insulin. His insulin requirement was 75 units daily. These trials, together with animal experiments, disposed of fears that such doses would demand a proportionately huge supply of carbohydrate. Instead of the 100 Gm. of starch and sugar it was learned that any small amount, such as 10 Gm., would act temporarily as an antidote for 750 or 1,000 units of insulin but that these feedings had to be repeated, because the patient was unable at any one time to eat enough to give protection through the entire duration of the effects of such a dose. Protection was afforded by a series of intravenous injections of dextrose of only 10 Gm. each. The blood sugar curves indicate that the effects of the insulin lasted for about twenty-four hours. This duration was not appreciably changed by alterations in the amount of carbohydrate used as an antidote or by the high or low level of blood sugar during this time. The patient experienced hunger and faintness only when there was marked hypoglycemia. Otherwise he felt well. In particular, the absence of disturbance of appetite or digestion at all times appears significant as indicating that these doses were well within the bounds of safety and that they did not establish the maximal limit of insulin tolerance in this individual. The foregoing doses failed to produce symptoms of intoxication, indicating that the tolerance of many persons must be higher than this. On the other hand, doses of only a few units can

produce the typical condition in predisposed persons. The insulin dosage which can be tolerated without intoxication in the foregoing sense has been determined more or less accurately for several animal species. For a strong man it is probably above 15 units per kilogram of weight. For the dog and cat it appears to be less than this. For the rabbit it is from 35 to 40 units per kilogram, for the mouse 1,000 units, and for the rat from 2,000 to 4,000 units. For birds it is still higher. This series may offer some support for Sakel's hypothesis, in showing lower insulin tolerance of the species having greater development of the higher nervous centers. The fact that patients sensitive to insulin are usually nervous while those with higher resistance are more phlegmatic may, if generally confirmed, be significant from the psychiatric as well as the general physiologic point of view. No animal ever succumbs to insulin hypoglycemia while eating up to the capacity of a normal hungry individual of the species—loss of appetite always precedes any dangerous symptoms. The high tolerance of strong or average persons confirms the prevailing view of the non-toxicity of insulin for them up to an extremely high limit, but it does not imply that similar doses can be given safely to weak or sensitive individuals.

Gas Gangrene.—Mitchell and his associates sent a questionnaire to the superintendents of all general hospitals of fifty or more beds in New York state requesting the following information: number of gas gangrene infections in the hospital during 1932 to 1936 inclusive, description of injuries or conditions and their care preceding the infection, time elapsing between injury and recognition of infection, bacteriologic confirmation, x-ray diagnosis, surgical care and general treatment, specific treatment results obtained, statement regarding need and value of serum, and suggestions and comments. The total indisputable gas gangrene infections for the five years number 135. Seventy-three additional cases were reported in which the diagnosis was doubtful or the data were incomplete. Predisposing factors have been arranged in the 135 cases. Nine diabetic patients had gas gangrene following amputation and died. Four arteriosclerotic patients had gas gangrene following amputation and three died. Six diabetic patients had gas gangrene before surgical treatment and three died. Seven deaths were listed under pregnancy. Nine patients received prophylactic injections of antitoxin and two died. These two fatalities probably resulted from damage other than gas gangrene infection. Eighty-four patients received therapeutic injections of serum and twenty-nine died. If the data submitted regarding gas gangrene are accepted, they indicate that infection by this group of spore-bearing bacteria are probably as frequent as tetanus. It is hoped that the statistics offered, incomplete as they are, will be of value in determining whether gas gangrene antitoxin should be prepared and supplied by the state department of health.

Dementia Praecox Without Insulin Therapy.—Whitehead discusses the outcome by 1936 of 105 consecutive admissions, during the fiscal year 1931-1932, of dementia praecox. This allows a minimal observation period of five and one-half years. None of the patients were treated with insulin. The diagnosis was changed in three cases; 6 per cent of the patients died, 42 per cent have been returned to the community and 52 per cent are in hospitals. In the sixty-four cases diagnosed hebephrenic the improvement rate was found to be 51.5 per cent with 1.5 per cent recovery, 21.8 per cent much improvement and 28.2 per cent improvement. In the thirty-one paranoid cases the total improvement rate was 48.2 per cent with no recoveries. The cases of simple and catatonic type were too few to permit satisfactory conclusions. Exacerbation of symptoms necessitating readmission to the hospital among those discharged was found to occur in nine, or 21 per cent, of the forty-two discharged patients. Five of these were from the much improved and four from the improved groups. Of these nine who were readmitted only two remain in the hospital, the other seven having been discharged again. These results were more favorable than those of a similar series of cases surveyed after one year of observation and insulin treatment. In the latter 69 per cent were found to be unimproved, compared with 49 per cent in the five year survey. Comparison with results achieved by routine institutional measures plus insulin therapy shows a marked increase in the recovery rate and a marked diminution in the percentage of unimproved patients in the series treated with insulin. The percentage of improved and much improved patients is virtually the same with or without insulin.

- *Mortality During Periods of Excessive Temperature. Mary Gover.—p. 1122.
Poliomyelitis: Prevalence Since 1915 and the Present Situation. B. C. Hampton.—p. 1143.

Mortality During Excessive Temperature.—Gover discusses the weekly mortality rates from all causes for eighty-six large cities during the months of May, June, July, August and the first part of September of 1925 and 1930 to 1937 and

gives figures, curves and tables. In five of these nine years there are clearly defined peaks which occurred in the weeks ended June 13, 1925, July 4, 1931, July 28, 1934, July 18, 1936, and July 17, 1937. Slight increases in mortality occurred during July in 1930 and 1932 and during the first week of August 1933. During the summer of 1935, however, and the summers of 1926 to 1929, weekly rates of mortality from all causes did not show any marked deviations from normal. The week of maximal mortality occurred in July in six years and during the first part of June and the first part of August, respectively, in two other years. A comparison of maximal summer rates with a summer normal and with a normal for January, in all cities combined, is 12.5 actual rate and 10.2 normal rate per thousand of population (annual basis) for week ended July 4, 1931, and respectively 12.3 and 10 for July 28, 1934, 17 and 10.1 for July 18, 1936, and 12.3 and 10 for July 17, 1937. The actual normal rate for January is 12.6, based on the four weeks ended Jan. 27, 1934. During three of the four years the maximal summer rate was about equivalent to a normal January rate and exceeded it in 1936 by 4.4 per thousand of population. The foregoing weekly rates are weighted averages of the rates in the total number of cities, and thus the size of the death rate in the peak week is influenced by the area which was most severely affected. The area of high mortality was largely confined to the eastern coast cities in 1925 and 1937 and to the North Central section in 1931 and 1934. Although the rates for the affected individual cities in 1934 were greater than similar rates in 1937, the rise in the curve for all cities combined is about as great in 1937 as in 1934, owing to the concentration of the population in the East, which was the area of high mortality in 1937. Mortality which is certified and recorded as due to "excessive heat" includes by no means all excess deaths which occur during periods of extreme temperature. During July of 1934 in Kansas, "excessive heat" accounts for only about one fourth of the excess of deaths which occurred during that month. The remainder of the excess was distributed largely among diseases of the heart, cerebral hemorrhage, nephritis and pneumonia. Daily maximal temperatures for groups of cities and for individual cities in affected areas show that the excess in mortality is preceded by at least several successive days of extreme temperature. Excess mortality during a second period of extreme temperature in any one year is slight when compared with the excess mortality during the first major heat wave of the summer, even when the second rise in temperature is extreme.

Intestinal and Peritoneal Tuberculosis.—Mayer and Dworkin discuss the effect that roentgen and ultraviolet irradiation have on intestinal and peritoneal tuberculosis, their effect on animal and human tissue, the indications and technic of

usage in accordance with the pathologic changes, the clinical applications and comparative clinical results. The use of roentgen and ultraviolet radiation for treatment of intestinal and peritoneal tuberculosis is often productive of good results, warranting more general use of these measures as adjuvants to rest and hygienic treatment. A trial of tumor dosage of x-rays under careful supervision is indicated in proliferative forms of intestinal and peritoneal tuberculosis that have not responded to smaller doses. With roentgen treatment, best results are obtained in hyperplastic and simple proliferative forms of intestinal and peritoneal tuberculosis, especially when applied early in ascitic forms of peritoneal tuberculosis. With ultraviolet therapy, both natural and artificial, the ascitic and proliferative forms of peritoneal tuberculosis as well as the proliferative and ulcerative forms of intestinal tuberculosis are generally responsive in patients not too critically ill.

*Painful Shoulder in Association with Coronary Artery Disease. C. B. Leech, Providence.—p. 104.

Painful Shoulder and Coronary Disease.—Four patients with painful shoulders associated with disease of the coronary artery led Leech to a consideration of the possible causal relationship of the two conditions. Several articles concerned with this association have been found in the literature. The general opinion seemed to be that the association is too frequent to be accidental. The majority of the patients had pain in the left shoulder and anginal pain referred to the left arm. Three of the author's patients had pain in the shoulder to which the anginal radiation was referred, in two of them the right shoulder; in the fourth the anginal pain was substernal only. Painful shoulders are uncommon in forms of cardiac disease other than that due to sclerosis or occlusion of the coronary arteries. It is not difficult to distinguish pain of the shoulder from that of angina pectoris. The anginal pain is usually relieved by glyceryl trinitrate, while pain of the shoulder continues even though it may have been intensified during the anginal attack. Pain of the shoulder is not aggravated by exercise such as walking but there is marked limitation of movement of the arm; neither the shoulder nor the arm tolerates weight bearing. In the author's four patients the difficulty of the shoulder disappeared as general improvement in the cardiac condition came about; apparently as the coronary blood supply improved, the disability of the shoulder improved also. Diathermy and salicylates gave but little relief. That the site and radiation of anginal pain may be affected by extracardiac lesions is well recognized and there may be a somewhat similar reciprocal relation between pain of the shoulder and disease of the coronary artery; if so, the underlying condition in the girdle of the shoulder remains difficult to detect. If the pain of the shoulder is due to some sort of reflex stimulation, it seems

logical to consider it as much a part of the cardiac picture as the angina pectoris itself and it is logical to judge by its disappearance that some improvement in the myocardial blood supply has occurred. In the absence of other definite causes for such disabilities of the shoulder and arm, disease of the coronary artery should be suspected and searched for by the usual methods.

*Quantitative Serologic Test for Syphilis. W. W. Williams, Denver.—p. 612.

Quantitative Serologic Test for Syphilis.—Williams has devised a quantitative test for syphilis based on Kolmer's modification of the Wassermann reaction and the principle involved is the use of graduated amounts of the serum to be tested. The amounts of serum used are 0.2, 0.1, 0.05 and 0.001 cc. The test is reported as 4 plus if all four amounts are positive, 3 plus if three are positive, 2 plus if two are positive, and 1 plus if only one is positive. If with the largest amount of serum (0.2 cc.) there is some degree of hemolysis, the result is reported as doubtful. This quantitative estimation of the amount of antibodies present in the serum is of practical value, he believes, in determining the result of therapy in cases in which treatment is being administered.

Otitis Media and Mastoiditis in Infancy.—Of the 1,324 infants less than 1 year old admitted to the Alder Hey Children's Hospital during 1936, McConkey and Couper found that 195 (14 per cent) suffered at one time or another from otitis media or otitis media and mastoiditis. In a certain proportion the otic infection was undoubtedly secondary to some other pathologic process. The remainder were cases in which the infection appeared to be responsible for the child's illness and in which, in the majority, suitable treatment of the ear resulted in improvement. The latter is called primary. Any doubtful case was included in the secondary group. In the secondary group (seventy-four cases) associated with respiratory infections the greatest number of cases and the highest death rate (31 per cent) occurs in the age group from 3 to 9 months, while in the group (twenty-one) associated with nutritional disturbance the greatest number occurs in the age group from birth to 6 months, with a death rate in this group of 45 per cent. In the group associated with nasopharyngitis (twelve cases) the greatest mortality (33 per cent) was in the age group from birth to 6 months. In the nine cases of otitis media complicated by another infection there were four fatalities. The previous method of feeding these children does not appear to influence the results. There were no deaths in the seven cases of primary classic mastoiditis. In the thirty-three primary cases of otitis media and mastoiditis the death rate was 84.8 per cent and the highest death rate appears to be in the age group from 1 to 3 months. All of the thirty-nine children with mild primary otitis media and mastoiditis recovered. Among the patients with classic mastoiditis only one was breast fed for more than three months, while the remainder all had shorter periods of breast feeding. In the toxic group the highest death rate occurred among the infants with no or less than one month of breast feeding. Operation is always indicated in classic mastoiditis and the results are good, in the toxic group the results are poor and in the mild group the results are good in selected cases. Once the infant's infection so overwhelms it as to produce symptoms of toxicity, its chances of survival are just as great with conservative treatment as with surgical intervention. The analysis of the seasonal incidence of the primary group shows that the greatest numbers occur during the months of July, August, September and October, the season of the year when diarrhea and vomiting are most prevalent in infancy. Confirmation is afforded for the theory already advanced by numerous authors that the well known diarrhea and vomiting syndrome is frequently caused by the presence of otitis media and latent mastoiditis, the pathology of which is of the nature of a retention phenomenon with lack of satisfactory drainage.

Benzedrine in Mental Disease.—Anderson gave benzedrine orally to thirty-three patients with minor forms of mental disorders in daily doses ranging from 5 to 45 mg. and to eight normal subjects. In fifteen it was found necessary to discon-

tinue the drug because of untoward effects. In two others the drug appeared to be of no value and was discontinued. In eleven a beneficial effect could be claimed, in some cases with reservations. In five no mental, physical and psychic effect was produced. Of the eleven patients who appeared to benefit from the drug only three had no physical symptoms—that is, the drug appeared to exert its effect in the psychic sphere alone. The principal symptoms were headaches, giddiness and cardiovascular symptoms. Of the normal subjects one had decreased frequency of micturition, another increased frequency, two had pain in the chest, one had palpitation, one had some anorexia, one felt giddy and tired and in one there were no physical symptoms. As for the effect of the drug on different psychiatric conditions, the best results were obtained with the depressed patients. The drug is perhaps of greatest value in the terminal stages of a depression—that is, when clinical improvement has already appeared. With regard to sleep, the results were variable. Of the normal subjects all but two experienced an increase in mental or physical activity. It is difficult to claim any great therapeutic value from benzedrine, but its use relieves the depressed patient even transiently and gives him a few hours' respite. It should be used cautiously.

Placental Extract in Measles.—Of 205 girls in a girls' school under the care of Parish, eighty-nine had not had measles. January 18 one child was found to be in the incubation stage of measles. Contacts were widely spread throughout the school. Prophylactic measures were discussed and placental extract was used in an attempt to modify the subsequent attacks and to lower the complication rate. By the end of the term (April 3) seventy-five of the eighty-nine susceptible girls had measles, as well as five of the 116 said to have had measles previously, two of whom had also received a prophylactic injection. The extract had no effect in preventing the attack of measles. Figures show that among the susceptible cases measles developed in 93 per cent of those who had been given the modifying injection and in 75 per cent of those who had not. The epidemic was of moderate severity, although there was a remarkable freedom from serious complications. The only complication of any severity was one case of suppurative otitis media.

Sulfanilamide Compound as Prophylactic in Puerperal Infection.—During 1937 Hayes and Sami administered *p*-benzyl-aminobenzene sulfonamide (proseptasine) prophylactically in all emergency cases of puerperal infection admitted to the hospital. From January to June 1937 they gave two tablets three times daily (3 Gm.) for four days. From July to December 1937 they gave four tablets three times daily (6 Gm.) for four days. There was a reduction of morbidity due to genital sepsis from 22.16 per cent (1935) and 16.94 per cent (1936) to 11.45 per cent in 1937, during which time the drug was given prophylactically. This reduction occurred chiefly in the abnormal cases: the membranes were ruptured and infection was potential or apparent, the patient had been in labor from a few hours to a few days, obstetric shock was usually present, multiple vaginal examinations or attempts at delivery had been practiced or the case was usually terminated by means of an obstetric operation. No ill effects have been observed as a result of the

administration of the drug; as much as 125 Gm. has been administered without signs of toxic symptoms. The authors suggest that larger doses of the drug be used. Although a reduction of 5 per cent in morbidity is not striking, they feel that it is encouraging enough to advocate further investigation with increased dosage.

Postarsphenamine Blood Dyscrasias.—Rajam and Tampi encountered three cases of postarsphenamine blood dyscrasia in treating 18,620 cases of syphilis (64,101 injections of arsenicals). Recovery in case 1 confirms the observation of other workers that usually thrombocytopenic cases run a benign course and respond well to ordinary therapeutic measures. The platelet count in this case was much lower than that enumerated in any other case so far. Though the patient was on his way to recovery it cannot be stated that complete regeneration of the platelets had occurred. When he was discharged the count was only 50,000 per cubic millimeter. The symptoms in this case started two days after the last injection. Case 2 represents a typical secondary aplastic anemia with all the blood elements employed. The severe type of aplastic anemia caused in this case may have been the result of fudin or *p*-oxyacetylaminophenylarsinate of diethylamine (acetylarsan) or a combination of the two. Neoarsphenamine was employed in case 3. Agranulocytosis was the most prominent feature. Examination of the bone marrow showed the aplastic condition of the hematopoietic system. Possibly if the patient had lived longer a better clinical picture of aplastic anemia might have developed. In cases 2 and 3 there were no lesions in the throat which are usually associated with low neutrophil counts. The futile attempts at treatment are shown by the two fatal cases. Undue bleeding from the gums during the arsenical treatment offers a clue in some cases to this group of disorders. It is perhaps worth while to do a preliminary blood examination in debilitated patients and in the occasional cases in which spreading and sloughing of the lesion take place in spite of antisyphilitic treatment. The earliest evidence of damage to the hematopoietic system calls for prompt withdrawal of further medication with arsenic. Epinephrine is used in platelet deficiency; calcium, thiosulfate and liver preparations may be used as a routine. Bleeding may be stopped by symptomatic measures. Regeneration of the leukoblastic tissues is now attempted by using pentnucleotide and similar preparations. Repeated blood transfusion may tide over a crisis and give time for other measures to be adopted in the regeneration of the hematopoietic system. No further arsenical injections are to be given in the cases in which recovery has occurred. Recurrence is said to be invariably fatal.

Serum and Sulfanilamide in Meningitis.—Banks reviews three groups of cases of meningococcal meningitis: (1) thirty-eight acute cases treated with serum (meningococcus antitoxin) intensively by the venous, lumbar, cisternal and occasionally ventricular routes (from December 1933 to April 1937), (2) fifty-nine acute cases treated with intravenous serum and sulfanilamide by mouth (from May 1937 to May 1938) and sixteen acute cases treated exclusively with sulfanilamide by mouth (from April to June 1938). The fatality rate during the first five days in the first group was 16 per cent. There were no infants in this series. The cerebrospinal fluid was usually sterile within twenty-four to forty-eight hours, but in about

a fifth of the cases meningococci were present for four or five days, or occasionally longer. In the fifty-nine cases including ten infants treated with both serum and sulfanilamide, the fatality rate was 11.8 per cent. Recovery was rapid and the nursing relatively easy, the cerebrospinal fluid being usually sterile within twenty-four hours. The few exceptions to this rule, as well as two of the seven deaths, could be explained on the basis of low dosage of sulfanilamide. In the sixteen selected cases treated with sulfanilamide alone there were fifteen rapid recoveries. Sulfanilamide therapy has changed the treatment of meningococcal meningitis from a difficult to a relatively simple matter. The former high case mortality in infants appears to be yielding to this treatment. High initial dosage is advocated. The sulfanilamide level in the cerebrospinal fluid should preferably reach 5 mg. per hundred cubic centimeters in twenty-four hours and be maintained at this level for three days. Early cyanosis is not an indication for reducing the dosage. The treatment is probably effective only in the acute stage. Two patients treated after the tenth day of the disease died. Experimental and clinical evidence so far is in favor of combined serum and drug therapy, especially in severe cases.

Counterirritants in Pleural Disorders.—Working on the assumption that the counterirritant applied to the skin caused an inflammatory process in the subcutaneous tissue and in the parietal pleura whereby the reticulo-endothelial cells would undergo an increase in number, Puder sought to demonstrate the increase of these cells by means of an intravenous injection of an electronegative, i. e. an acid, dye which would become stored in the reticulo-endothelial cells. The experiments were performed on four rabbits. The rabbit treated with mustard paper showed no distinct microscopic changes. In the second animal the area of skin treated with potassium iodide ointment containing free iodine showed ulceration and demarcation of the ulcer; the parietal pleura showed some imbibition. In the rabbit treated with tincture of iodine the skin as well as the deeper tissues and the pleura were stained a deep blue, which was less marked on the control side. There was also found in the skin an exogenous pigment probably due to the iodine. The parietal layer of the pleura was saturated with serum, the right lung showed signs of congestion and there was moderate hyperemia under the visceral layer of the pleura. The macroscopically visible changes resulting from the application of a mixture of lactic acid, orthophosphoric acid and volatile acids dissolved in alcohol and glycerin correspond to those in the rabbit treated with iodine, except for the loss of cutaneous epithelium caused by the application. Microscopic examination showed changes in the skin, hyperemia of the subpleural parts of the lung and transudation of serum into the parenchyma of the lung. From the experiments it is deduced that certain substances applied to the skin of the chest may lead to hyperemia, transudation and venous congestion in the visceral pleura and even in the lung parenchyma of the side to which they have been applied.

Phrenogastric Syndrome of Coronaritis.—Laubry and his associates report five cases of the phrenogastric syndrome of coronary origin. In some patients who present either the antecedents of acute coronary thrombosis or the characteristic electrocardiographic changes of a coronary lesion there develops an elevation of the left side of the diaphragm, frequently in association with an aerogastria or an aerogastrocoly. The elevation may be moderate, that is, the left half of the diaphragm may be lifted simply to the level of the right half; in other cases, however, the elevation is so great that the roentgenologic aspect is identical with that after phrenicectomy on the left side. In most but not in all cases, the diaphragmatic elevation seems to be accompanied by modifications in the gastric morphology; the stomach may present an abnormal gaseous distention or, when the diaphragmatic elevation is great, a folding of the small curvature may result. The clinical diagnosis of the phrenogastric syndrome of coronary origin is made in various ways. In some patients the coronary thrombosis is known and the aerogastria is diagnosed secondarily at the time of a roentgenologic examination; in other patients it is the roentgenologic detection of aerogastria which suggests a coronaritis, the latter being then affirmed by the electrocardiogram. To explain the phrenogastric syndrome of coronary origin, the authors suggest several hypotheses. The phrenogastric symptoms may be of the nature of a reflex to the irritative factor of the coronary lesion. Moreover, the coronaritis may elicit the changes by way of the left phrenic nerve, which is in contact with the pericardium. The authors regard as most important the role of the irritation of the pericardium, mediastinal pleura and diaphragm. They show that grave prognostic errors can be avoided if, in the presence of diaphragmatic elevation, accompanied by gaseous distention of the stomach, a search is made for signs of coronary lesions and the patient is subjected to systematic electrocardiography.

Treatment of Cerebrospinal Meningitis.—Muraz and his associates report their experience in the treatment of cerebrospinal meningitis in epidemics that occurred in French Nigeria. Of forty-seven patients who were treated with serum, thirty-seven were cured. They report four cases treated with the chrysoidin derivative rubiazol by mouth as well as intramuscularly. Of the four patients, two were cured. The authors describe their experiences with para-amino-phenyl-sulfanilamide (lysococcine) administered by mouth or intraspinally. During the first two days as many as sixteen tablets (four times four) were given daily (each tablet 0.3). During the following six or ten days, about half of that dose was administered (four times daily two tablets). The average number of tablets given to adults in the course of the entire treatment was 100. They emphasize the simplicity of the oral administration of the sulfanilamide preparation and say that this treatment reduced the mortality to 16.39 per cent; that is, the mortality was less than in serotherapy. They stress that sulfanilamide treatment is much less expensive than serotherapy. The combination of serotherapy with oral sulfanilamide treatment, which was employed by other investigators in twenty-three cases, resulted in cure in twenty-one of them.

Achresthic Anemia.—Wilkinson says that a megalocytic hyperchromic anemia may exist in conditions other than pernicious anemia. In earlier reports (1935, 1936) he, together with Israels, described eight cases to which they applied the term "achresthic anemia." The patients have dyspnea, palpitation and fatigue but there is no appreciable loss of weight. In contradistinction to the lemon-yellow color of the skin in pernicious anemia, the skin of these patients is rather a brownish yellow. There is no history of lingual sensitivity or ulceration, of poor digestion, of flatulence and of intestinal disturbances, and there are no neurologic or hemorrhagic symptoms. There may be an increase in the size of the liver and spleen; cardiac murmurs and an increase in the size of the heart may also occur. The gastric secretion is practically normal. The examination of the blood reveals a hyperchromic megalocytic anemia, generally grave (from 1 to 2 million erythrocytes), with an increased color index and with a variable degree of anisocytosis and poikilocytosis. The course of achresthic anemia is chronic; treatment may prolong life by months or as much as two years, but the patient never regains his health completely. Injection of liver extract should be tried, because it will furnish diagnostic information, but the doses must be larger than in pernicious anemia. It is preferable to divide the doses; treatment by depots is not indicated in achresthic anemia. If no reticulocytosis is produced or if there is only a slight increase in the number of erythrocytes, blood transfusions must be repeated until an adequate red cell count is attained. Maintenance treatment must always be energetic and should consist in injections of liver extracts (from 4 to 8 cc. weekly or more) or in the administration of desiccated stomach preparations in doses of 30 Gm. a day. When relapses occur, blood transfusions must be repeated; their effect is only temporary and as the disorder progresses they seem to become less effective. Splenectomy is contraindicated in achresthic anemia. The author says that achresthic anemia seems to be a primary disorder. It has not been possible to trace it to a hemolytic poison, to a toxemia or to another factor. Studies revealed a strong hyperplasia of the hematopoietic organs with a megaloblastic predominance. The author suggests that in achresthic anemia the hematopoietic tissues are incapable of assimilating the antipernicious factor that is present in the depots of the organism.

Acute Erythremic Myelosis.—According to Di Guglielmo, acute erythremic myelosis (acute erythremia) is a disease with well defined clinical and histopathologic aspects. He lists the following as the characteristic aspects: (1) a grave anemic state from the beginning of the disease, (2) irregular fever or more often remittent fever, (3) splenomegaly, which is nearly always considerable, (4) hepatomegaly, which is nearly always less severe than the splenomegaly, (5) acute evolution, the disease lasting generally from one to two months and always having a fatal outcome, (6) the presence of a larger or smaller number of mostly basophilic erythroblasts in the peripheral blood, (7) primary hyperplasia of the erythropoietic tissue with arrest of the maturation in the primary phases of cellular evolution, and (8) proliferation of the elements of the reticulo-endothelial system. In the typical cases these symptoms are always faithfully reproduced, but this disease like other morbid processes appears also in incomplete and atypical forms. The diagnosis is comparatively easy. The etiology is completely unknown. The mode of onset, the development and the clinical aspects suggest an acute infectious process, but all investigations (serologic tests, hemocultures, inoculations of necroptic material into various mediums and so on) have given negative results. The disease occurs in both sexes and in all ages. The prognosis is unfavorable. All the typical cases described so far failed to respond to treatment with liver, arsenic, iron or blood transfusion and all ended in death.

Serous Meningitis in Pfeiffer's Glandular Fever. W. Huber.—p. 892.

Serous Meningitis in Pfeiffer's Glandular Fever.—Huber says that the combination of Pfeiffer's glandular fever with meningeal symptoms cannot be regarded as rare, for of ten patients with glandular fever observed at his clinic three had a noticeable meningism. Lumbar puncture disclosed in two of these three cases pathologic aspects of the cerebrospinal fluid of a nature indicating a lymphocytic meningism. In the third case the cell count of the cerebrospinal fluid was at the limit of normality but there were no other changes. Five other patients with glandular fever but without signs of meningism were subjected to spinal puncture; in three of these the pressure of the cerebrospinal fluid was found increased; in two the cell count was increased and in two pathologic protein curves were detected. These changes in the cerebrospinal fluid without clinical signs of meningitis are of interest because they indicate a high incidence of involvement of the meninges in Pfeiffer's glandular fever. This meningeal involvement is probably due to a great affinity of the still unknown causal agent for the central nervous system. The author states further that, whereas two of his three patients with glandular fever and meningism presented the typical signs, the third case illustrates with what severity the meningeal symptoms may appear in glandular fever. He gives a detailed clinical history of this case. He further directs attention to the great variations in the symptomatology of glandular fever, pointing out that some of the symptoms may be severe or moderate or even entirely absent. However, in order to arrive at the diagnosis it is usually considered that the following should be present: febrile course, involvement of the lymphatic apparatus and the characteristic blood picture; the latter is regarded as the most important for the diagnosis. The blood picture of glandular fever is characterized not by a simple lymphocytosis but rather by qualitative changes in the lymphatic elements.

Bronchopneumonia in Infants.—Pouché made bacteriologic studies on sixty infants suffering from primary bronchopneumonia. Cultures were done with the pharyngotracheal secretions and with the material taken from the lung or the pleural cavity by puncture, either during life or immediately after death. Hemocultures were also made. In some cases any of the foregoing procedures was repeated or cultures with two different materials were done. Several bacteria, especially pneumococci of type IV and hemolytic streptococci were identified. The author found that cultures with the pharyngotracheal secretion are of scanty diagnostic etiologic value. Noncausal bacteria frequently appear in the cultures. Hemocultures are also of scanty diagnostic value. Cultures from lung or pleural material showed in all but one of the author's cases pneumococci of type IV and hemolytic streptococci. The former was predominant in the cases which evolved to recovery whereas the latter was predominant in the cases which ended in death of the patient. According to the author the disagreement of authors in the literature as to the etiology of primary bronchopneumonia in infants depends on the various methods used in the bacteriologic researches. The disease is caused by pneumococci of type IV. Pneumococcus antisera do not control the disease because of the fact that up till now they have been prepared with pneumococci of types I, II and III, which are not the etiologic agents.

Ulcer and Gastroduodenitis in Splenomegaly.—According to Greppi and Forconi, gastric, duodenal and gastroduodenal inflammation and passive congestion associated with similar conditions of the spleen and the liver show an early phase of gastric, duodenal or gastroduodenal ulcer. The condition is frequent in man. The lesions predominate in the duodenum, rarely in the stomach. The clinical symptoms vary from mild to grave digestive disturbances. In certain cases there is either gastralgia or the complete syndrome of gastric or gastroduodenal ulcer. In all cases the chemistry of the gastric secretion is altered and there is a tendency to the production of local hemorrhages. Roentgen examination of the gastrointestinal tract shows the various evolutionary phases of gastric or gastroduodenal ulcer from simple duodenitis to typical ulcer. The authors report nine such cases. Roentgen examination of the gastrointestinal tract showed simple or erosive duodenitis in seven cases, phlogosis of the stomach and cardias with perivisceritis in one case and a chronic ulcer of the lesser curvature of the stomach with perivisceritis in another. In all cases the clinical symptoms corresponded to the evolutionary phase of the ulcer. In one case the repeated examination of the gastrointestinal tract showed simple duodenitis, which evolved to erosive duodenitis with formation of punctiform niches in four months. In another case, roentgen examination showed the regressive evolution of a small juxtapyloric ulcer to diffuse gastroduodenitis in the course of four months of medical treatment. The authors believe that inflammation and passive congestion of the spleen alone or in association with similar conditions of the liver are due to local disturbances of the preportal circulation. The condition results in the establishment of a special form of diffusing and progressive inflammation and local passive hyperemia, which induces the development and evolution of gastric, duodenal or gastroduodenal ulcers.

*Some Endocrine Influences on Fat Metabolism of Culture of Human Leukocytes. G. Wallbach.—p. 230.

Treatment of Adiposogenital Dystrophy. A. Margitay-Becht.—p. 241.

Endocrine Influences on Fat Metabolism of Leukocytes.—Wallbach says that in earlier studies he was able to show that the fat metabolism can be observed on the culture of human leukocytes. Even under normal conditions, staining with sudan III will reveal the depositing of fat in the human leukocytes undergoing growth and differentiation in cultures. The author thinks that these fat deposits can probably be explained by infiltrative processes of the plasma lipoids and by the splitting off of lipoids from lipoid-protein compounds. The fat metabolism undergoes fundamental changes when lipoids are added to the culture medium. However, there is not necessarily an increase in the fat deposits following the addition of certain lipoids. Rather there is evidence that the culture of leukocytes has a certain autoregulation as regards its lipid metabolism, because some fats, such as liquid petrolatum or milk, cause a reduction in the fat deposits of the growing human leukocytes. Such manifestations seem to suggest that not only the lipoids but also stimulating substances contained in them play a part in the absorption of fat by the leukocytes. The aim of the investigations described in this report was to determine the influence exerted by some endocrine and chemical substances on the fat metabolism of cultures of human leukocytes. The author experimented with some preparations of the thyroid, of the testes, of the pancreas, of the adrenals and of the hypophysis; also with sodium taurocholate, pepper

and phlorhizin. Contrary to expectations, the addition of thyroxine to the culture did not cause a reduction in the lipid deposits but rather a tremendous increase. Insulin was found to cause finely granulated fat deposits in the cells during the first five days. During the later stages of cultivation, considerable fat deposits could be observed in the macrophages and fibroblasts. Hypophylin produced a great increase in the lipid deposits. Epinephrine produced finely granulated fat deposits during the first five days of the culture; on the sixth day the increase in fat deposits was especially great, but after that the fat deposits disappeared temporarily. In the presence of an extract of the testes the cellular fat deposits were moderate on the first day; during the following five days there was slight increase, but in the end all fat deposits had disappeared. Phlorhizin was found to cause a temporary but pronounced increase in fat deposits. Bile caused at first moderate deposits, then a great increase, but finally there was a consumption of intracellular fat. Pepper caused a disappearance of the fat deposits. The author further reports how the simultaneous addition of lipoids and glandular products or other stimulating substances acts on the intracellular fat metabolism. He found that the same glandular preparations and stimulating substances may differ in their effects on the fat metabolism, depending on the lipoids that were administered simultaneously. Regarding the significance of these observations, the author says that an increase in fat deposits does not necessarily indicate an increased fat metabolism. Under certain conditions the absence of fat deposits may indicate an especially active metabolism.

Electrocardiographic Tests on Children.—Laurentius says that in children the early recognition of latent cardiac defects is of especial importance. Children develop cardiac defects chiefly during diphtheria and during acute rheumatic polyarthritis. During the acute stages of these disorders the diagnosis of the cardiac defects is usually simple, but later the estimation of the functional capacity of the heart may cause considerable difficulties. In this paper the author reports electrocardiographic studies on forty-four children. Of these thirty had had a diphtheric myocarditis, twelve had had a rheumatic polyarthritis and two had congenital cardiac defects. Each child was subjected to three electrocardiographic tests: one was made while the child was at rest, one immediately after physical exertion and one three minutes after exertion. It was found that the electrocardiogram made after exertion is a valuable aid in the functional examination of the heart in that it often permits the recognition of latent cardiac defects. Summarizing his observations in the course of the electrocardiographic tests, the author says that he observed wandering of the origin of the impulse, occurrence of intra-auricular conduction disturbances, partial retardation of the conduction between auricle and ventricle, frequent appearance of extrasystoles and signs of myocardial impairment. His investigations showed that although the electrocardiographic record made while the child is at rest is normal and clinical signs are absent, there are nevertheless a certain number of children in whom the electrocardiogram that is made after exertion will reveal pathologic changes. From these observations he concludes that all children who have had a diphtheric myocarditis should be protected against exertions for a time so as to avoid undesirable complications. In apparently compensated valvular lesions after articular rheumatism, disturbances are also often detected in the electrocardiogram that is taken after exertion. These children likewise should be protected against exertion. Strenuous gymnastics and sports and similar

exertions should be avoided for a time. Only after all pathologic signs have subsided may the children be permitted a gradually increasing amount of exertion.

Necessity of Repeated Roentgen Examinations in Case of Late Manifestations of Tuberculous, Bronchogenic Dissemination. H. Bartsch and S. Zollner.—p. 1078.

Menstrual Disturbances in Genital Infantilism.—Klöppner reports observations on 190 women with genital hypoplasia and disturbances in the menstrual cycle. These 190 cases were observed among 510 women with genital hypoplasia. With the exception of thirteen cases in which there existed only a hypoplasia of the uterus, the genital infantilism was generally characterized by a low perineum, hypoplasia of the labia, narrow vagina, low vaginal vault, small uterine cervix and body, high position of the ovaries and small parametrium. The author observed also that genital infantilism is not restricted to certain structural types. It was found in persons with various bodily builds, but it seemed especially frequent in the somewhat masculine types. Regarding the incidence of genital infantilism, he says that in the years 1929-1933 it was almost twice as high as in the years 1907-1918. He thinks that the deficient nutrition during the war years is probably the chief cause of this increase, for the condition is especially frequent among the women who at the time of the insufficient nutrition were in the stage of their first sexual development. However, this deficient nutrition is not the only cause. Among the author's material there was evidence that considerable inbreeding might be an important factor in genital infantilism. Discussing the menstrual disturbances in the women with genital hypoplasia, he says that they occurred in 37 per cent (190 of 510). Among these 190 cases there were ten of primary amenorrhea, twenty-nine of secondary amenorrhea, twenty-two of hypomenorrhea, thirty-two of oligohypomenorrhea, twenty-four of menorrhagia and seventy-three of metrorrhagia. In view of the fact that a late menarche was formerly regarded as one of the characteristics of genital infantilism, it seems surprising that thirty-six of these 190 patients had a relatively early menarche and that 103 had a normal menarche. Of the ten patients with primary amenorrhea, eight had a rudimentary uterus and six had signs of a generalized infantilism. In the women with secondary amenorrhea the anamnesis often revealed a late menarche. Painful menstruation was complained of by 141 of the women. The author thinks that in order to determine the nature of the menstrual disturbance a microscopic examination of the endometrium is essential; in the material that is discussed in this paper, curettage was done in 128 cases. After giving tabular reports of the results of these examinations, he discusses endocrine therapy of the menstrual disturbances concurring with genital hypoplasia. He thinks that, in cases of hypomenorrhea and oligomenorrhea, estrogen may at first be tried alone. However, he warns against the indiscriminate use of estrogen in all cases of genital hypoplasia with menstrual disturbances, pointing out that in cases of cystic glandular hyperplasia progesterin is required and that in cases of amenorrhea both progesterin and estrogen have to be given.

Thrombopenia in Benzene Poisoning.—Kern says that impairment of the hematopoietic organs is one of the symptoms of chronic benzene poisoning. However, there is not always a uniform impairment of the various functions of the bone marrow. Impairment of the leukopoiesis seems to be most frequent, but anemias with considerable inhibition of the erythropoiesis have likewise been observed in a number of cases, and reductions in the number of thrombocytes with a tendency to hemorrhages has been noted in some cases. The impairment of all functions of the bone marrow is comparatively rare in human subjects; it occurs only in the severest cases. It is difficult to estimate

the incidence of thrombopenias in benzene poisoning, because in many of the cases reported in the literature a counting of the thrombocytes had been neglected. However, hemorrhages and scurvy-like symptoms dominated the clinical picture in many cases of chronic benzene poisoning, and investigators who did take a thrombocyte count often discovered thrombopenias. In none of the cases previously reported was a severe thrombopenia the only manifestation of an impairment of the bone marrow, and so the author feels justified in reporting the history of such a case. The patient, a farmer aged 58, had benzene poisoning while working with a defective benzene motor in an insufficiently ventilated building. Study of the blood picture revealed that the thrombocytes decreased to zero and then increased again above the normal level. The thrombopenia was accompanied neither by leukopenia nor by anemia. The case is noteworthy also because of the involvement of the central nervous system in the form of a bilateral spastic paralysis of the arms and legs and somnolence. The author thinks that the paralytic symptoms were probably the result of multiple hemorrhages into the central nervous system; the fact that the paralytic symptoms appeared at the time when the hemorrhagic diathesis was in its severest stage, and the observation that the nervous disturbances subsided and the cutaneous hemorrhages disappeared after the thrombocytes had reached a normal level again, seem to corroborate this. After the paralytic symptoms subsided sciatica developed, but this too subsided again after several weeks.

*Excess Mortality of Boys as Result of Recessive Sex-Linked Hereditary Factors. F. H. Haase.—p. 105.

Hypertension in Uniovular Twins.—Klemola reports the discovery of essential hypertension in twin sisters aged 23. He thinks that the case is noteworthy not only because essential hypertension is rare at such an early age but also because no such case has as yet been reported in twins. After reporting the clinical histories of the twin sisters, he cites factors which indicate that the twins were enzygotic. Then he discusses the role of heredity in essential hypertension in the light of research on twins. In this connection he cites authors who demonstrated in studies on twins that the blood pressure values of uniovular twins have a greater similarity than have those of binovular twins. In the twins whose histories are reported, the essential hypertension was discovered in 1934, when they were 23 years of age, but it is probable that they had had it several years before. Moreover, they have been under observation during the four years since 1934 and the blood pressure has remained uniformly elevated in recent times (160-210 mm. of mercury). It is noteworthy that roentgenoscopy has failed to disclose a hypertrophy of the heart, but this absence of cardiac hypertrophy has been noted by others in young persons with essential hypertension. On the other hand, electrocardiography disclosed signs of myocardial defects, probably the results of attacks of myocarditis, which may have concurred with the repeated attacks of angina, to which the twins had been subject. By means of the work test, considerable changes could be elicited in the electrocardiogram which were identical with those in coronary insufficiency. The family history of the twins indicates that this was a case of recessive transmission of hypertension.

Excess Mortality in Boys.—Haase reports statistical studies on the excess of the mortality in boys over that of the mortality in nurslings in general. Previous to the decade covered by his statistics, such studies had been carried on by Lenz and later by Schirmer. Haase observed the same relations between the figures as had those investigators. He shows tables which indicate that the mortality of nurslings has decreased in all countries in recent decades but that the excess mortality of boys has increased everywhere. A comparison of the statistical reports of different countries reveals that a high excess mortality for boys corresponds to a low nursing

mortality and vice versa. Moreover, if different years are compared it can be seen that according as the excess mortality of boys is the lower, the higher is the nursing mortality and vice versa. The author says that his observations are a further corroboration of the theory suggested by Lenz, that the excess mortality of boys is chiefly the result of recessive, sex-linked hereditary factors. As is explained by Lenz, such hereditary factors do not have to be frequent to result in an excess mortality of boys. For instance, if it is assumed that the X chromosome of human subjects contains 250 hereditary units, this signifies an excess mortality of 2.5 for 100 if one of every 10,000 units is recessively lethal. Recently Lenz further amplified his theory, stating that the suspected pathologic hereditary factors may be stable or unstable as regards the environment. If most of them are stable in this respect, a high excess mortality for boys must be expected in the presence of a low nursing mortality because, if the mortality of nurslings is low, the fatalities that do occur are chiefly caused by internal, hereditary causes; that is, the excess mortality of boys must become especially noticeable. In addition to the theory of Lenz, the author also cites views and observations of von Pfaunder, Landauer and Rietz. He shows that Landauer's objection to the theory of Lenz is not tenable.

Habitual Dislocation of Patella. B. C. Wösten.—p. 3337.

Treatment of Postencephalitic Parkinsonism.—Broekema first describes the observations he made in Penegrossi's clinic in Rome, pointing out that at this and several other Italian clinics postencephalitic parkinsonism is treated with an extract of the root and the rootstock of *Atropa belladonna*. The extract has an alkaloid content of 0.02 per cent and is prepared from plants that have an especially high alkaloid content. After describing how the extract is prepared, the author discusses the mode of administration. At the onset of the treatment the doses are small; that is, from 1 to 2 cc. is given. Gradually the quantities are increased. The optimal doses vary greatly (between 6 and 300 cc. a day). The average daily dose for women is from 60 to 90 cc., for men from 60 to 120 cc. The larger doses are fractionated, the largest quantity being given in the evening, so that the headaches likely to result from medication with the belladonna extract will concur with the period of sleep. In the beginning of the treatment it may also be desirable to give the extract by clysmia; this form of administration has the same effect as the oral one. Complete intolerance for the extract is extremely rare. During the treatment the patients should abstain from smoking, alcohol and coffee. The diet should be chiefly vegetarian. Moderate exercise in open air, massage, gymnastics, psychotherapy to overcome the depression and work therapy have to be combined with the belladonna therapy. After giving a summary report about the results obtained with this treatment in 1,346 cases in Rome, the author gives detailed clinical histories of four patients treated by him. He shows that the improvement appears in some patients sooner than in others. All his patients had previously been treated unsuccessfully with other measures. The author hopes that this treatment will find a more general application in the Netherlands.

CORRECTION

Myelomatosis.—In the abstract from *Hospitalstidende*, Copenhagen, entitled "Myelomatosis," published on page 760 of the August 20 issue of *THE JOURNAL*, the sentence which read "In the two cases of hyperproteinemia and hyperglobulinemia and hypoglobulinemia there was abundant Bence Jones protein in the urine" should have been as follows: "In the two cases with hyperproteinemia and hyperglobulinemia the urine did not contain Bence Jones protein; in the other two cases, with hypoproteinemia and hypoglobulinemia, there was abundant Bence Jones protein in the urine."

HISTORICAL ASPECTS OF IRON THERAPY IN ANEMIA

CHAIRMAN'S ADDRESS

RUSSELL L. HADEN, M.D.

CLEVELAND

Iron is an essential part of the hemoglobin molecule. It is the most valuable remedy in the treatment of an anemia in which the primary defect is a deficiency in hemoglobin. While iron has been prescribed for almost three centuries, its therapeutic use is far older than the rational explanation of its action, and opinion concerning its value has changed greatly from time to time. Physicians long ago prescribed iron for chlorosis, a disease first described in 1520 by Johannes Lange. Later, others taught that medication with inorganic iron was worthless. Only recently have clinicians learned anew the most effective preparations and methods of administration.

To Sydenham¹ (1624-1689) belongs the credit for introducing iron into clinical medicine for the treatment of anemia. Iron salts had been employed by physicians for other purposes since the time of Hippocrates. The earlier applications of iron were more often symbolic, with the idea that iron was indicative of strength and was imbued with some peculiar force by Mars, the god of war. Iron was even designated mars by the alchemists. It seemed logical that a condition characterized by weakness, as is anemia, should be treated with a remedy suggesting power or strength.

Sydenham included chlorosis under the general head of hysteria, which he said "is the commonest of diseases next to fever." In speaking in 1681 of the treatment of the chlorosis of hysteria he said: "All which showed that the chief curative indication is the restoration of the blood—the fount and source of the spirits." He suggested bleeding and purging and continued:

After these evacuations I comfort the blood and the spirit belonging to it by giving a chalybeate 30 days running. This is sure to do good. To the worn out or languid blood it gives a spur or fillip whereby the animal spirits which before lay prostrate and sunken under their own weight are raised and excited. Clear proof of this is found in the effect of steel in chlorosis. The pulse gains strength, the face (no longer pale and death-like) a fresh ruddy color. Here, however, I must remark that with weak and wornout patients the bleeding and purging may be omitted and the steel be begun with at once.

From the Cleveland Clinic.

Read before the Section on Pharmacology and Therapeutics at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 16, 1938.

1. The Works of Thomas Sydenham, translated from the Latin by Dr. Greenhill, edited by R. G. Latham, London, Sydenham Society, 1850, vol. 2, p. 97.

Sydenham preferred to give the "steel in substance." His next choice was "iron or steel filings steeped in cold Rheinish wine." He also said that chalybeate water used for the same purpose was nothing more or less than iron in liquid form. Two prescriptions which he suggested contained from $7\frac{1}{2}$ to 15 grains (0.5 to 1 Gm.) of iron filings to be given daily, which would certainly be effective in the treatment of an iron deficiency anemia.

For the next 150 years iron continued to be used for the treatment of anemia but with indifferent and varying results. Lemery and Geoffroy in 1713 demonstrated for the first time iron in the ash of the blood.² In 1746 Menghini found that the iron of the blood could be increased by feeding iron-containing food.³ These discoveries came long after Sydenham's therapeutic application of iron but provided a rational basis for the use of iron. Crocus martis was recommended in doses of 10 to 40 grains (0.6 to 2.5 Gm.) for dropsy and green sickness (chlorosis) in "A Compleat History of Drugs," translated from the French of Pierre Pomet by Lemery and Tounefort and published in London in 1712.² The crocus martis was prepared by exposing plates of iron to dew, by sprinkling iron filings with rain water or water and honey or by heating iron white hot and plunging it into melted sulfur.

Pierre Blaud,³ however, first emphasized the specific action of iron in the treatment of chlorosis and suggested a method of iron medication which has never been improved on. Blaud's original paper appeared in 1831, many years before a red blood count was first done or a hemoglobin estimation was first made. Blaud even recognized the essential nature of chlorosis. He thought that the disease "arises from a faulty formation of blood as a result of which the blood is an imperfect fluid or the coloring matter is defective so it is no longer suitable for stimulating the organism and maintaining the regular exercise of its functions." He then said that iron preparations restore to the blood the most important principle which has been lost, its coloring substance, and suggested the use of a combination of iron sulfate with potassium carbonate which "has never foundered in our hands."

Blaud reported the treatment of thirty patients, all of whom were cured in from ten to thirty-two days, and said that previous failures had been due to the use of too small a dose of iron: "Who has not seen chlorotics pine away for an entire year although they have been subjected to the prolonged influence of iron

2. Christian, H. A.: A Short Sketch of the History of the Treatment of Chlorosis with Iron, *Med. Libr. & Hist. J.* 1: 176-180, 1903.

3. Blaud, Pierre: On the Chlorotic Maladies and on a Method of Specific Treatment of These Affections, *Rev. méd. franç. et étrang.* 1: 337, 1832.

water or of ferric hydrate?" He emphasized that his excellent results were due to the use of the preparation he recommends and the large dose.

Blaud's original prescription was as follows:

Ferrous sulfate	5 ss
Potassium carbonate	3 ss

Pulverize separately the two substances to a very fine powder, then blend very exactly. Add mucilage tragacanth, pound strongly, and make into a mass which will be divisible in forty-eight pills.

This prescription gives the equivalent of 5 grains (0.3 Gm.) of ferrous sulfate, or approximately 2 grains (0.1 Gm.) of ferrous carbonate, in each pill.

The method of administration suggested was:

1, 2, 3 day	one pill before breakfast and at bedtime.
4, 5, 6 day	one pill three times a day
7, 8, 9 day	two pills in the morning and evening
10, 11, 12 day	two pills three times a day
13, 14, 15 day	three pills twice a day
16 and follow- ing days	four pills three times a day

Blaud thus used from 6 to 25 grains (0.4 to 1.6 Gm.) of ferrous carbonate daily, or the equivalent of from 15 to 60 grains (1 to 4 Gm.) of ferrous sulfate. He suggested that the favorable action of his prescription was due to the finely divided state of the ferrous carbonate and the addition of potassium carbonate. He emphasized the two important principles of iron therapy—the use of a ferrous salt and large doses. Little has been added since to these fundamental principles of iron medication. A year after his original communication Blaud⁴ criticized a formula suggested by Cotterau, saying:

I am so anxious that so precious a remedy which has never failed in my hands and which I consider as a specific in chlorotic diseases be employed in suitable doses to obtain the complete success from it. I am hastening to communicate to you the manner of preparation which I have always used.

He again described the dosage and repeated his original prescription.

Blaud deserves a prominent niche in the history of the development of iron therapy. He was born in 1774, at Nîmes, graduated in medicine in 1804, practiced all his life in Beaucaire and died there in 1858.⁵ Many modifications of his formula have been suggested, usually under the name "Blaud's pills," so it is often impossible to tell from the name just what the pill contains. The official method of preparation described in the French codex medicamentarius differs little from the original method of preparation. Pierre Blaud's nephew, August Blaud, a chemist, made a specialty of these pills⁶ over the entire world under the name "veritable pills of Doctor Blaud." The formula in the British as well as in the American pharmacopeia differs from the original in composition and in the dose recommended.

For many years the fundamental principles of iron therapy introduced by Blaud were followed. Thus Felix von Niemeyer,⁷ whose textbook of medicine was for many years the Bible of German medicine, stated

that he followed the principles outlined by Blaud with great success. He used the following prescription:

Ferrous sulfate	3 ss
Pulverized potassium carbonate and tartrate	3 ss
Tragacanth to make.....	96 pills

Each pill is equivalent to 2½ grains (0.16 Gm.) of ferrous sulfate. He suggested from three to five pills three times a day. He said of chlorosis:

Three boxes cures the most persistent case. At Magdeburg and Greifswald I often had to send my recipe for the pills for a great distance, my good fortune in the treatment of chlorosis—to which by the by I owe to the rapid growth of my practice—having given me a great reputation as the possessor of a sovereign remedy against the disease.

He went on to say that it was argued that large doses of iron were not necessary, but he continued:

The number of patients who have recovered in my practice through the employment of Blaud's pills after they had taken small doses of tincture of iron and wine of iron for years without positive effect and had repeatedly visited Pyrmont and Dubing is large enough to warrant the assertion that we shall cure chlorosis most speedily and surely by means of ferruginous preparations which can be tolerated in large doses and of these Blaud's pills stand highest in the list.

Immerman⁸ in 1877 stated that "large doses [of iron] cure chlorosis far more certainly and quickly than small ones." He also emphasized that the dose is far more important than the compound selected. He recommended ferrous sulfate in a prescription and dosage similar to Blaud's.

Osler⁹ in 1892 said "I have for years in the treatment of chlorosis used with the greatest success Blaud's pills made according to and given according to the formula in Niemeyer's textbook in which each pill contains 2 gr. of the sulphate of iron." He suggested from one to three pills three times a day.

About 1890 a definite change in iron therapy began to take place. Smaller doses of iron were used, poorer results were obtained and the opinion became widespread among clinicians that iron was of little value in the treatment of anemia. There were several reasons for this change. Bunge¹⁰ taught most dogmatically at this time that inorganic iron was converted into sulfide and not absorbed from the intestinal tract and so could not have any beneficial effect on anemia. He suggested the use of organic iron only. Although MacCallum¹¹ demonstrated that inorganic iron was absorbed from the upper part of the intestinal tract and Stockman¹² proved that iron sulfide would relieve anemia, Bunge's teachings influenced iron therapy profoundly. Perhaps the most important influencing factor, however, in stopping the use of large doses of iron was the teaching of Quincke¹³ and of von Noorden¹⁴ that no more than 1½ grains (0.1 Gm.) of metallic iron daily was necessary in the treatment of chlorosis. These clinicians in

turn were probably influenced by the demonstration that only a few milligrams of iron are actually metabolized each day.

As a result of such teachings, iron began to be used only in small doses, with little effect, so clinicians really believed that iron was of no value in the treatment of anemia. Williamson and Ets¹⁵ as late as 1925 thought they had proved experimentally that iron does not influence anemia produced in rats and dogs by bleeding. They stated as a result of their experiments that "inorganic iron is absorbed and may be found in the liver and spleen but is not converted into hemoglobin" and concluded that "in the light of the foregoing experiments the administration of inorganic iron has no therapeutic value in anemia." Further experimental studies have demonstrated the error of these conclusions. Thus Heath, Strauss and Castle¹⁶ have shown that the iron absorbed by a person with iron deficiency anemia is converted quantitatively into hemoglobin.

Recently the value of large doses of iron if iron is needed has been emphasized anew by numerous workers. One of the first was Lichtenstein,¹⁷ who showed in 1918 that the anemia of the premature infant responded to large doses of iron. Meulengracht¹⁸ in 1923 suggested large doses for the treatment of the anemia of adults on the basis of Lichtenstein's work. He used 45 grains (3 Gm.) of reduced iron daily, or thirty times the dose thought sufficient by Quincke and von Noorden. Even before Meulengracht, Lindberg¹⁹ had shown that the anemia of influenzal infections responded to large doses of iron. Now every clinician recognizes the value of iron and the need for giving large doses.

The most recent development in iron therapy has been the renewed emphasis on the greater potency of ferrous salts. While any iron preparation is effective if given in large enough doses, very much less of the ferrous compounds needs to be taken.²⁰ Thus the two fundamental principles of iron therapy, large doses and the use of a ferrous salt, now generally accepted, only confirm what Bland, Niemeyer, Immerman, Osler and others thought and practiced. These principles, forgotten by clinicians for many years, have only recently been learned anew. Such rediscoveries emphasize again our debt to the great clinicians of the past.

The All-Vegetable Diet.—There have been careful and thorough investigations of the nutritive possibilities of the all-vegetable diet. There are various combinations of plant materials that will keep a human being alive, after a fashion, but no combination has been found which will provide "optimum" nutrition for the omnivorous animals that human beings are. While strict vegetarianism is possible it is unsatisfactory and more than a little difficult. There is no exact explanation of this except the generalized one that animal proteins have more nearly the same combinations and proportions of the amino acids which we need than do the vegetables.—Furnas, C. C., and Furnas, S. M.: *Man, Bread and Destiny*, New York, Reynal & Hitchcock, 1937.

SURGICAL LESIONS OF THE ADRENAL GLANDS

WALTMAN WALTERS, M.D., D.Sc.

AND

EDWIN J. KEPLER, M.D.

ROCHESTER, MINN.

Tumors involving the adrenal gland may take their origin from the cells of the adrenal cortex, which originates from the mesoderm of the wolffian body or the medulla, which originates in structures giving rise to the sympathetic nervous system. The most frequently occurring adrenal tumor is that involving the cortex. Several excellent summaries of reported cases have appeared in the literature. To the signs and symptoms thought to be pathognomonic of such tumors, Gallais¹ has applied the name "le syndrome génito-surrénal," and Krabbe² that of "adrenal hirsutism."

In general, it may be said that one of the chief characteristics of tumors of the adrenal cortex is their tendency to produce changes in the sexual characteristics of the person affected. This characteristic is not what one would expect from a study of adrenal insufficiency, as the outstanding features of this condition are disturbances in electrolyte metabolism which usually are not associated with any marked alterations in the primary or secondary sexual characteristics. It is not at all clear why adrenal tumors should function in this fashion. Embryologic and chemical studies have thrown some light on the problem. Since the gonads and the adrenal cortices have a common embryologic origin, it is not surprising to find that the two structures have cells with common histologic characteristics and secrete hormones which have similar chemical formulas.³ It is not inconceivable therefore that the cells of tumors of the adrenal cortex may secrete compounds which have the properties of male and female sex hormones in addition to the properties of the hormone or hormones which influence electrolyte metabolism and are essential to life. After removal of this type of adrenal tumor the secondary sexual characteristics have reverted essentially to normal, as described by Collett,⁴ Holmes⁵ and ourselves.

Although there are a variety of tumors which originate in the medullary substance of the adrenal gland, the most important surgically are the paragangliomas, which frequently are called "pheochromocytomas." They are benign in character and are characterized clinically by attacks of paroxysmal hypertension and the subjective symptoms associated with it. The similarity of origin of the sympathetic nervous system and the adrenal medulla explains paroxysmal hypertension, the characteristic symptom of these medullary tumors.

From the Division of Surgery (Dr. Walters) and the Division of Medicine (Dr. Kepler), the Mayo Clinic.

Read before the Section on Surgery, General and Abdominal, at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 15, 1938.

2. Krabbe, K. H.: The Relation Between Adrenal Cortex and Sexual Development, *New York M. J.* 114: 4-8 (July 6) 1921.

3. The chemical similarity between the members of the group of male and female sex hormones has been appreciated for some time. More recently it has been shown that hormones of similar chemical structures, which are capable of maintaining the health of adrenalectomized animals, can be extracted from the adrenal cortex.

4. Collett, Arthur: Genito-Suprarenal Syndrome (Suprarenal Virilism) in a Girl One and a Half Years Old, with Successful Operation, *Am. J. Dis. Child.* 27: 204-218 (March) 1924.

5. Holmes, Gordon: A Case of Virilism Associated with a Suprarenal Tumor; Recovery After Its Removal, *Quart. J. Med.* 18: 143-152 (Jan.) 1925.

Excellent results have persisted for many years following removal of adrenal paraganglioma, as reported by Mayo,⁶ Shipley,⁷ the Porters⁸ and Walters.⁹

ADRENAL CORTICAL TUMORS

Symptoms and Diagnosis.—The symptoms depend on the age and sex of the patient at the onset of the illness, the type of tumor, the degree of its endocrine activity and the duration of the disease. Adrenal cortical tumors occur most frequently among young women, although in our series of eight cases two of the patients were children; one was 9 years of age and the other 2. In twenty of the reported cases the patients were males and in fourteen of these cases the patients were boys.

When a hyperfunctioning tumor occurs after puberty, the changes which tend to reverse the sex occur, such as virilism of women and feminism of men. By virilism is meant the appearance of masculine, and the recession of feminine, physical and mental traits. The menses cease, there is an excessive growth of hair on the face and body, the breasts atrophy, the clitoris enlarges and the entire habitus may change to the masculine type. On the other hand, when the disease originates among children, precocious puberty usually occurs. Among boys the precocious puberty is likely to be of the masculine type with the precocious development of external genitalia of the mature type. Among girls the puberty is heterologous; that is, it tends to progress along masculine lines with hypertrophy of the clitoris, deepening of the voice, masculine distribution of hair and, interestingly enough, sometimes with precocious menstruation. In one of our cases, the patient, who was a child aged 2 years, had had two or three menstrual periods.

Difficulty in diagnosis arises from the fact that in some instances the symptoms resulting from adrenal cortical tumors may resemble closely those that occur in Cushing's disease (basophilic adenoma of the pituitary body). The latter disease occurs for the most part among young women, and in contrast to adrenal cortical tumors (which vary in their clinical manifestations) produces a rather constant clinical picture. In pituitary basophilism the clitoris usually is not enlarged, but absence of this finding does not exclude a tumor of the adrenal cortex. At the present time there is no single clinical criterion which can be used to differentiate the two conditions. The consequence of this fact is that the presence of an adrenal cortical tumor should be excluded in all cases in which the symptoms of Cushing's disease are present. To our minds, this is most accurately done by exploration of the adrenal glands. At the same time, when it is desired, one can open the peritoneal cavity and examine the ovaries to exclude the possibility of masculinizing tumors of the ovaries (usually arrhenoblastoma) and, very rarely, granulosa cell tumors which result in the male type of hirsutism, amenorrhea and hypertrophy of the clitoris. However, such tumors practically never cause diabetes, hypertension, osteoporosis or the other incidental symptoms associated with adrenal cortical tumors.¹⁰

In children, tumors and inflammatory processes in the region of the pineal body and contiguous structures

may be associated with sexual and somatic processes. Finally there are, in addition, many women who have varying degrees of the hirsutism, hypertension and debility for which no adequate basis can be found.

Laboratory Aids.—Routine laboratory studies have been of little aid in the differential diagnosis of these tumors. Frank¹¹ recently has reported a very high concentration of estrogenic substance, equal only to that encountered in pregnancy, in the urine of four patients who had adrenal cortical carcinomas. Negative reactions were encountered in specimens of urine obtained from fifteen patients who had some symptoms of pituitary basophilism or who had the adrenal cortical syndrome. In this group of fifteen patients one had a hypernephroma, one had an adrenal medullary paraganglioma, one had an adrenal cortical adenoma, and one had adrenal hyperplasia. Frank concluded that "it seems likely that adrenal cortical carcinoma alone of adrenal tumors increases the amount of estrogenic substance in the urine to as high as from 1,000 to 10,000 mouse units per liter, with a negative pregnancy test." In the cases in our series the results of this test were negative. It however was not performed in all cases. It would appear, therefore, that a positive Frank test would strongly favor a diagnosis of adrenal cortical carcinoma but that surgical exploration should not be deferred because of absence of large amounts of estrogenic substance in the urine. Substances which have the properties of the male sex hormone have been found by a number of workers in the urine of patients with adrenal cortical tumors. Use of this finding in diagnosis cannot be made until more information is available regarding the occurrence of such substances in the urine of normal women and patients suffering from diseases other than those involving the adrenal cortices.

Cahill and his associates¹² recently have emphasized a diagnostic procedure, introduced by Carelli,¹³ by which the adrenal glands are delineated in roentgenograms which are made after the injection of air into the perirenal fascial space. Our experience with this procedure has been very limited and we are not in a position to pass final judgment on its merits or its limitations. In some of the cases reported in the literature, satisfactory visualization of an adrenal tumor by this method was obtained when the pyelograms were normal. It is interesting to note that in the case reported by Lukens and others¹⁴ "the residual emphysema from the air injection was an added source of difficulty" during operation.

We feel that in case of doubt the adrenal glands should be explored surgically, provided the clinician is familiar with the early symptoms of acute adrenal insufficiency and if adequate facilities are at hand for treatment of this emergency should it arise. There are two objections to this point of view: First, an appreciable number of patients will be disappointed because no benefit results from the operation; second, it has been stated that in cases in which advanced symptoms

of basophilism are present there is considerable danger of infection. In our experience this has not interfered with postoperative progress in cases in which cortical tumors were not found; in two cases Cushing's disease was discovered at necropsy months after the patient had been dismissed from observation. Certainly there is very little justification for the death of patients who receive roentgen therapy of the pituitary body when the lesion responsible for their symptoms is an adrenal cortical tumor which might have been eradicated successfully had the patient been operated on early in the course of the disease.

Treatment.—The treatment of these lesions is, of course, surgical removal of the tumor; this has been accomplished in seven cases at the Mayo Clinic without any mortality.¹⁵ Two of these tumors were very large and weighed 600 Gm. and 800 Gm. respectively, while the others averaged approximately 2 to 4 cm. in diameter. Although microscopic examination showed early malignant changes in all the tumors, in five cases the tumor was definitely encapsulated and recurrence has not taken place. In the two cases in which the tumors were very large, penetration had extended beyond the capsule; the growth was attached to the diaphragm in one case and to the inferior vena cava in the other case. In both cases the lesions were malignant; there were signs and symptoms of recurrence and both patients died within two years after the operation.

The most important factor in surgical therapy, to our minds, is the anticipation, prevention and control of postoperative adrenal cortical insufficiency. This consists essentially of the preoperative and postoperative administration of potent extracts of the adrenal cortex¹⁶ and parenteral and oral administration of adequate amounts of a solution of sodium chloride and sodium citrate and the administration of a diet that is low in potassium. These procedures tend to control the impending adrenal cortical insufficiency which has probably been responsible for the high mortality (50 per cent previously reported by Lukens and his associates, by Cahill and his associates and by Scholl¹⁷). The method outlined is essentially that which at the clinic has been found to be effective in controlling various degrees of adrenal insufficiency in Addison's disease and has been used in all our cases of suspected adrenal cortical tumors. Its effectiveness is illustrated by operative recoveries in seven cases; in two of the cases the adrenal glands on the opposite side were found to be atrophic. It must also be remembered that the outstanding characteristic of any hyperfunctioning adenoma is its tendency to produce its hormone irrespective of the needs of the body for this hormone. The remaining nonadenomatous endocrine tissue of the type from which the adenoma took its origin can be expected to hypofunction. This remaining nonadenomatous tissue may be functionally inadequate or be actually atrophic on histologic examination. By tiding the patient over the crisis with the administration

of potent adrenal extracts and by concentrating the sodium ions in the body, it has been our experience that eventually the nonadenomatous endocrine tissue will regain its capacity to produce a sufficient amount of hormone to meet the needs of the body as regeneration occurs. In brief, postoperative adrenal insufficiency should be anticipated and should be prevented by continuous treatment throughout the postoperative period; during the entire postoperative period the patient should be watched carefully for any premonitory signs of acute adrenal failure. Among the more important signs of such failure are anorexia, hiccup, nausea, vomiting, weakness, insomnia, apathy or restlessness, an increasing pulse rate and a falling blood pressure. Pyrexia accelerates the development of adrenal insufficiency and is therefore poorly tolerated. These clinical manifestations may precede any material change in the chemical composition of the blood. The blood pressure should be recorded every four hours and the concentration of blood sugar, plasma chlorides and blood urea should be determined daily. If, at any time, the condition of the patient is the least suggestive of adrenal insufficiency, more vigorous treatment should be instituted or treatment should be resumed if it has been discontinued. It is not generally appreciated that fatal adrenal failure can develop within a few hours. In consequence of this fact it is easy for the physician to be lulled into a false sense of security. A good rule of thumb to remember is that danger lies in undertreatment rather than in overtreatment.

ADRENAL MEDULLARY TUMORS

Signs and Symptoms.—Adrenal medullary tumors occur with much less frequency than those involving the cortex and few cases have been reported in the literature. Paroxysms of hypertension accompanied by vasomotor phenomena such as pallor, tachycardia, headache and apprehension are the characteristic symptoms associated with adrenal medullary tumors. Sweating is another of the vasomotor phenomena which occurs in some cases, although sweating does not occur after an injection of epinephrine. Precipitation of these paroxysms is obtained by undue physical and mental exertion and they can be precipitated experimentally by the "cold test"¹⁸ (the introduction of the feet or the hands in water at a temperature of 4 C. for one minute). The appearance of the patient and the physical signs are of little help in making the diagnosis unless the tumor is of sufficient size to be palpated during abdominal examination or to depress the kidney abnormally, as shown by urographic examination; this depression was not evident in four cases observed at the clinic. In one case, which recently was reported by Borch-Johnsen,¹⁹ the tumor had attained a huge size and weighed 3,000 Gm.

Patients with hyperfunctioning adrenal medullary tumors withstand surgical procedures very poorly. One of the characteristics of hyperfunctioning adrenal tumors is their tendency to cause sudden death. There are a number of instances on record in which the tumor was discovered accidentally at necropsy following sudden death after minor or major surgical procedures, such as extraction of a tooth, hemorrhoidectomy or amputation of a gangrenous extremity. Because of this

M., and Kepler, E. J.: The Suprarenal Cortical Syndrome with Presentation of Ten Cases, *ibid.* 100: 670-688 (Oct.) 1934.

16. We have been fortunate in having at all times an ample supply of potent extract prepared by Kendall. We have not had any recent first hand experience with any of the commercial preparations. Before using any one of the commercial preparations one should have had, if possible, some experience with its use in the treatment of acute adrenal insufficiency as it occurs in Addison's disease. The dosage necessary may be considerably larger than that recommended by the manufacturer.

tendency, patients with hyperfunctioning adrenal tumors stand surgical procedures very poorly.²⁰

Diagnosis.—Owing to the relative infrequency of tumors of the adrenal medulla, the possibility of their presence is not likely to be suspected. In one of the four cases seen at the clinic the diagnosis was made before operation and in another case the tumor was found following the unusual persistence of a hypertension subsequent to bilateral splanchnic resection. In the third case, which was reported by Dr. C. H. Mayo, the tumor was suspected preoperatively and was found at abdominal exploration. These three patients survived and no further paroxysms of hypertension have occurred. In the fourth case the tumor was found at necropsy. In one of these cases the hypertension was somewhat continuous rather than paroxysmal. It must be remembered that paroxysms of hypertension occasionally may occur in the absence of medullary cortical tumors. We have seen one such case in which the only important postmortem finding was petechial hemorrhages in the pons.

Thus far we have referred to the most important surgical lesions of the adrenal medulla, namely the paragangliomas, which are benign in character. Another benign tumor, the ganglioneuroma, produces no characteristic clinical symptoms and is usually found unexpectedly at necropsy. Malignant tumors which involve the adrenal medulla are the neuroblastomas which metastasize early to the liver and lungs in the adult and to the skull and long bones in children. The diagnosis of these lesions is usually made only after metastasis has occurred. Surgical treatment directed toward their removal is without benefit on this account. The usual preparation of patients for surgical procedures is all that is required preliminary to operation in cases of adrenal medullary tumors.

SURGICAL APPROACH TO THE ADRENAL GLANDS

Although transthoracic, transpleural and retroperitoneal approaches to the adrenal glands have been carried out, in our opinion the approach which gives the best opportunity for minute and careful inspection of the gland is through a posterolumbar incision similar to that used in exposing the kidney. After the fascia of Gerota has been incised, the perirenal fat is reflected from the upper pole of the kidney and the kidney is retracted downward; this exposes the inferior and posterior aspects of the adrenal gland. It is possible in this manner to study the gland accurately from every side without disturbing the circulation. Care is taken to prevent injury to the blood vessels which enter the adrenal gland on its mesial and posterior aspect. Although we have seen one case of small multiple adenomas, minute in size, in other cases adenomas have been recognized grossly with ease; these have varied from 2 to 15 cm. in diameter. When larger tumors are present, practically the entire adrenal gland may be thinned out and destroyed, with the exception of a fringe a few millimeters in length, which can be recognized by its brilliant yellow as being adrenal cortical tissue. It must be remembered that on the right side the adrenal gland will be found to be in direct contact with the inferior vena cava. Usually the blood vessels supplying an adrenal

tumor are much larger than the blood vessels which supply the normal adrenal gland. On this account, care must be taken to ligate them accurately.

SUMMARY

Symptoms produced by a tumor of the adrenal cortex depend on the sex and age of the patient at the time the tumor begins to function. These tumors are encountered most frequently among women and are characterized by variable changes in secondary sexual characteristics, such as cessation of menstruation, occasionally hypertrophy of the clitoris, abnormal growth of hair with masculine distribution and characteristic lesions of the skin such as a florid complexion accompanied by acne and purplish striations. Among girls, tumors of the adrenal cortex tend to produce precocious puberty which is more masculine than feminine in character. The disease seldom occurs among males, either young or old. It is characterized by precocious puberty of the masculine type in boys and by feminism in the male adult. The difficulty in making a diagnosis arises from the fact that the clinical picture is not pathognomonic. Similar clinical pictures result from any one of a number of diversified pathologic processes, such as hyperplasia of the adrenal cortices with or without thymic tumors, tumors of the gonads, and various intracranial lesions not directly involving the pituitary body. Routine laboratory studies have been of little aid in differential diagnosis although the presence of a high content of estrogenic substance in the urine is suggestive of the presence of adrenal cortical carcinoma provided pregnancy is excluded. Injection of air about the adrenal gland has been of aid in localizing some of the adrenal tumors. In forty reported cases in which operation was performed, the mortality was approximately 50 per cent. It is our opinion that the absence of mortality in seven consecutive cases in which operation was performed at the clinic is attributable to an increased understanding of the disturbance of physiologic processes which follows removal of almost all hyperfunctioning tumors of the endocrine system and to an increased knowledge of the pathologic physiology of Addison's disease. Improved methods of treating acute adrenal insufficiency have thereby been developed. These consist primarily of administration of large quantities of sodium chloride and sodium citrate, daily administration of an adequate amount of adrenal cortex extract and the use of a low potassium diet, throughout the entire postoperative period.

The most important medullary tumor is benign in character and is characterized clinically by attacks of paroxysmal hypertension. Reference has been made to four cases of adrenal medullary tumors seen at the clinic; in three of the cases operation was performed and the results were excellent.

In our experience, the most accurate surgical approach to the adrenal glands has been through retroperitoneal and posterolumbar incisions.

ABSTRACT OF DISCUSSION

DR. HOWARD C. NAFFZIGER, San Francisco: The authors have set forth clearly the clinical aspect of tumors of the adrenal cortex and of the medulla. The good results from surgical treatment are a great credit to the surgeon. I believe, however, that no small measure of the success is due to the preparation for operation and to the postoperative management. This should be stressed particularly. Without meticulous attention to the measures that have been recommended, surgical intervention will be associated with far greater risk. A diffi-

culty in diagnosis has been mentioned, namely differentiation of the symptoms of adrenal cortical tumors from those of Cushing's disease. There is an implication that a basophilic adenoma of the pituitary is responsible for the symptoms of Cushing's disease. Numerous anatomic, pathologic and biochemical investigations, however, have brought forth facts that stand in the way of complete acceptance of this view. One must not ignore the fact that in so-called basophilism of the pituitary gland there is either hyperplasia or an adenoma of the adrenal cortex. I have been inclined to the view that there may be two distinct clinical pictures associated with hyperfunction of the adrenal cortex, whether it is caused by hyperplasia or by tumor. First, there is the adrenogenital syndrome, in which there is reversal of sex. This is the picture which the authors have associated with adrenal cortical tumors. Second, there is Cushing's syndrome, in which I feel that the symptoms also arise from altered cortical function. In Cushing's disease there is evidence of overproduction of cortical hormone. Moreover, there are disturbances in electrolyte metabolism which differ from those found in Addison's disease. In cases of so-called basophilism, it is my feeling that the possibility of primary adrenal involvement must be kept continuously in mind, for most of the symptoms of the disorder are caused by such involvement. This is true regardless of the focal point in which the disease had its origin, and concerning which there is still plenty of opportunity for debate.

DR. HANS LISSER, San Francisco: A group at the University of California Medical School have for many years been intensely interested in these bizarre sexual endocrinopathies. There are a vastly greater number of patients who exhibit only some of the characteristic manifestations of the adrenocortical syndrome, mostly abnormal hirsutism, with perhaps lengthened intervals between periods but without actual amenorrhea, enlarged clitoris or hypertension. We have hesitated to advise adrenal exploration in the absence of a demonstrable lesion. Unfortunately no medical or endocrine therapy is of any avail in producing loss of the abnormal hair which is so embarrassing to many of these young women. Following Cahill's paper on "The Visualization of Adrenals by Injection of Air through the Perirenal Fascia, via Petit's Triangle," we undertook this diagnostic procedure, about two years ago. The tumor cases mentioned antedated the use of air. We have injected air in fifty cases during the last two years, obtaining wonderfully clear delineation of the upper poles of each kidney, but in only one instance have we been fortunate in demonstrating a definitely enlarged adrenal. Rarely is the tumor large enough to palpate, being tucked up deep under the diaphragm. We hoped that this maneuver would enable us to pick up tumors not large enough to feel or large enough to distort the pyelogram. We have had no unhappy complications from this procedure although occasionally patients have experienced a sense of pressure high up under the sternum immediately after the introduction of air, have become rather faint and cyanotic and have coughed for about fifteen minutes; we assumed that this came from either irritation of the diaphragm or the accidental introduction of air into the pleural cavity. I am inclined to question one statement made, that "very rarely, granulosa cell tumors result in the male type of hirsutism, amenorrhea and hypertrophy of the clitoris." Possibly a reference to this in the literature has escaped my attention; it is a most unlikely occurrence, however, since granulosa cell tumors elaborate large quantities of female sex hormone and therefore produce true sexual precocity in the little girl, menorrhagia in the adult woman and late menstruation in women of 60 to 70 years of age. It is not a masculinizing tumor. Unfortunately there is no "measuring stick" of adrenal function, such as exists for the kidney. Therefore in the presence of an adrenal tumor one is unable to estimate the functional integrity of the other adrenal. Consequently there is a decided element of risk in removing one adrenal and, as the authors have emphasized, death has followed if the remaining adrenal was inadequate. Most important therefore is the preoperative preparation and the postoperative watchfulness, described by Walters and Kepler, in avoiding and combating postoperative adrenal insufficiency during the week after operation.

DR. WALTMAN WALTERS, Rochester, Minn.: The point stressed by Dr. Lisser is well worth recording. Dr. Lisser has referred to danger of injection of air in the renal and adrenal regions. I am told that at the last meeting of the American Association of Genito-Urinary Surgeons two deaths were reported following injections of air. I used the method in three cases and was frightened in each one by the occurrence of spasm of the diaphragm, asthenia, cyanosis and air hunger and I have discontinued it. I think it is safer and of greater practical value in these cases to explore the suprarenal glands themselves. I agree also that in several of our cases the adrenal tumor was of insufficient size to be demonstrable by injection of air.

A CONSIDERATION OF PRESENT DAY NEWBORN NURSERY PRACTICE

SUGGESTIONS FOR IMPROVEMENT

MANDEL L. SPIVEK, M.D.

CHICAGO

Fatal diarrhea of the newborn occurring as a local hospital epidemic has within recent years been reported with increasing frequency.¹ In the face of such reports, it is conceivable that present day newborn nursery practices may not protect the infant from the introduction and spread of contagion. The increasing number of reports of such outbreaks justifies this appraisal of the nursery.

The term "newborn nursery" is used to identify that portion of the obstetric floor set aside for the care and common housing of the newborn. This consideration is not directed to any institution in particular but rather at nursery practice in general. This is an evaluation of the average newborn nursery in the average hospital.

The introduction of contagion may occur easily, sometimes obviously and at other times more subtly. The normal flow of traffic frequently is a potent source of danger. There is scarcely any group of patients in the hospital more thoroughly exposed than the infants in the nursery. Because of the concentration in one area, all infants are exposed to each nurse whether assigned to him or not; to each obstetrician, his own and his neighbors'; to each pediatrician, his own and the rest; to each orderly; to each laundry man; to each charwoman; to each janitor, and to every person who enters the nursery. The recently delivered infant covered with vaginal secretion and occasionally with maternal stool is another significant source of trouble.

The formula and other liquids given to the babies are not always above suspicion. Rigid care is not always exercised in their preparation or storage.

The question of infections of the upper part of the respiratory tract of mild degree among persons having business in the nursery is another problem. Its evaluation is difficult. Few institutions require that nurses and interns with "colds" or "sore throats" be put to bed or at least stay out of the nursery until well. Unfortunately, the physician is a chief offender. It is not unusual to see physicians with colds in the nursery, handling these infants, relying on masks to protect the infant and confine the infection to the carrier. If the

Read before the Section on Pediatrics at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

infection is due to a virus, it is difficult to see how several layers of gauze will stop the virus when a Berkefeld filter cannot. If the infection is bacterial, the known inefficiency of most types of masks after short periods of time² makes them ineffective. Fingering of masks and "on again-off again" tactics of the wearer complete the case against the mask as far as infections of the respiratory tract are concerned.

Little attention has been paid to the mother as a potent source of infection. In gonorrhea, how more intimately than from vagina to vulva, which occurs in the process of birth, can a newborn infant be exposed? Yet no special treatment is used to prevent the disease. How more easily can maternal bowel contents come in contact with the infant's mouth and subsequently its gastrointestinal tract than at the time of birth? How more intimately can an infant be exposed to a purulent infection of the skin than its own mother's acne, yet no special care is taken to protect it?

The enumeration of the sources of contagion is limited only by the imagination. The laundry, the innocent carrier, the insignificant skin lesion, the missed or sub-clinical gonorrhea, the unobserved, improperly functioning sterilizing equipment, the warm refrigerator, the plumbing cross of tap water and sewage may each have a varying degree of importance. From all these the individual infant must be protected. Yet few institutions are so set up that each and every avenue of approach is guarded and a routine check is made repeatedly.

The introduction of contagion into the nursery from without, while important, is relatively insignificant when the problem of transfer from patient to patient is considered. This transfer may occur with the greatest ease. Probably the most important single factor is the concentration of infants into one large unit called the nursery. This concentration is frequently nothing less than crowding. In a majority of nurseries the bassinets are arranged in convenient rows, touching each other at their sides or at best separated by a scant foot. In these instances the infants are separated from one another by the framework of the bassinet or a screening pad or cloth. This crowding, regardless of any of the intricacies of technic, is ideal for the spread of infection. It is impossible under these conditions to take or replace an infant without contaminating the neighboring bassinets. The changing of diapers, the disposal of regurgitated feeding, the changing of linen, the rearranging of positions all become impossible without the contamination of adjacent cribs.

In nearly all instances, the breaks in technic result in no harm. The errors are innocuous until a potent pathogen is introduced. The crowding then becomes a factor of spread rather than a factor of blockade.

The dressing table or work place is unimpeachable in theory alone. Few institutions require a complete change of sheets or other covering where an infant has lain. At most a clean diaper, easily wet through, is spread under the infant. Its shirt and other clothing are laid aside close by, contaminating other clean areas.

The neat tray of oils, cotton, powder and ointments may contain agents in the transfer of infection, not by the obvious contamination of their contents but by the more subtle contamination of their covers and outer surfaces. Few institutions require that these

materials be handled with freshly washed hands, tissue paper or forceps. Time frequently does not permit of such finesse.

The physician's and attendant's clothing must also be considered in the introduction and transfer of contagion. Providing gowns for nurses and physicians does not solve this particular problem unless an individual gown is used for each infant. Common gowns hanging in dressing rooms next to the physician's coat enhance rather than block the spread of infection.

Washing of hands before each procedure, no matter how simple, is only infrequently required. It is no uncommon sight to see an attendant change an entire group of babies while keeping the bottles propped on one another without any thought of using soap and water. The nurse, since she must handle the infants frequently, is a greater menace than the physician, especially in the understaffed nursery. Where adequate nursing service is provided, this factor is proportionately reduced. Yet at this point it is fair to question how a simple rinsing with soap and water, and rarely is it more than that, can possibly be adequate when surgical procedures require much greater thoroughness. On the other hand, no skin could possibly stand up under surgical scrubbing in a newborn nursery.

At this point the question of fairness or accuracy of this criticism of technic as now constituted may be considered. If the foregoing is granted, the relative infrequency of epidemic or even absence of epidemic in many nurseries might be looked on as an argument against this criticism. The absence of such a catastrophe in individual nurseries should be considered as due entirely to good fortune rather than to active vigilance. Once infection has gained entrance, only those who have been active in stamping it out can truly evaluate and appreciate the situation.

A certain few institutions have worked out elaborate technics, meticulous to a fine degree.³ This is especially true of nonobstetric nurseries. Every possible safeguard, check and block has been carefully considered and, in addition, machinery has been set up for its daily maintenance at a high standard of efficiency, with air-borne infection alone remaining uncontrolled. The recent development of ultraviolet ray traps may see even this eliminated.⁴ But these conditions exist in special instances. It is extremely doubtful, and experience in previous years supports the doubt, that such fine technics cannot exist without innumerable breaks. Investigation impartially conducted sometimes reveals that the technic has broken down completely during long periods with apparently no serious consequences.

Running through this entire consideration of present day methods of nursery technic and management appears one constant factor; that is, the nursery itself. The nursery as it is now known, with its crowding, its traffic, its communal equipment, its constant flow of easily infected and susceptible patients, is the thing at fault. It is the nursery that is wrong and not the technic. The control of contagion in such a group should be automatic and entirely free of the conscious effort of good technic and practice. The technics are adequate but the conscious effort to main-

tain them is the factor which breaks down. The care of infants should be so constituted that any accidental contaminant is blocked from further spread in the same manner that a fireproof building makes the spread of fire difficult. A fireproof building may burn but it does so with difficulty; likewise contagion might spread, but only with great difficulty.

The barrier that naturally suggests itself is the barrier of dispersion. The greater the dispersion of patients the more difficult becomes the spread of infection. The greater the dispersion of patients, the less the possibility of infection from direct or indirect sources. The wider the distribution, the less the possibility of contamination from obvious or obscure sources. At this point it must be emphasized that dispersion does not and cannot replace technic. It can only complement. It cannot replace.

The simplest form of dispersion, but at that the least effective of the methods of control, is that of treating each infant as a unit with complete equipment for that unit. This implies cubicle treatment, individual gowns, linen, locker, bedside stand, clothing, utensils and all the other necessities, all within easy reach of a wash stand, a method of treatment used in children and infant wards. The technic used would be that of the contagious unit. While this would be a step ahead, the dangers of "carriers" and the almost certain absence or ignoring of technic by a definite though usually small group of interns and very busy physicians would quickly make a mock of the technic unless it were guarded by a tyrant. Unfortunately this tyrant would be there only part of the time.

A dispersion of greater degree occurs if this cubicle system is used in conjunction with multiple nurseries of two to four baby capacity. In this scheme complete equipment for these infants in cubicles would form a unit close to or an integral part of a block of a similar number of maternal beds. This, of course, would mean wholesale alterations of existing obstetric floors but should be easy to incorporate in new structures.

Infection occurring in such a unit would be more readily confined and controlled than if it occurred in a nursery of twenty or thirty infants. A corollary to this method would be to house each baby in the mother's room. The objection to this method may have the weight of present day practice, but this is surely the more natural and to a certain extent more humane. Twenty minute visits every three or four hours is scarcely natural, nor will that be true after the mother and baby go home.

These methods of dispersion still have the objection of exposing the infant to a certain definite though diminished hospital traffic and to common services and supplies. They also imply redesigning and planning of obstetric floors. Further dispersion is possible and extremely desirable. The proposals to be cited may appear to be steps backward but should be considered as advances from positions now made untenable by experience.

The first proposal would be that of limiting the hospital stay to a much shorter period, ideally forty-eight hours or less after delivery. This would maintain for the physician the convenience of the hospital delivery but would limit contact to a shorter time.

The second proposal, the ultimate of dispersion, is frank old fashioned home delivery brought up to date.

What is to prevent some far-seeing, pioneering obstetrician from equipping a mobile obstetric unit so

complete and so cunning that all the advantages of the hospital could be had at home with none of the dangers inherent in the crowded nursery?

SUMMARY AND CONCLUSION

The spread of fatal diarrhea of the newborn raises the serious question of whether present day practices are entirely beyond reproach. Critical appraisal of housing, communal equipment, nursery traffic and technic show them in many instances to be faulty to a dangerous degree. Correction of these faults as they occur in the present setup is extremely difficult, especially if this correction follows lines of increased regulation or tightening of technic. Dispersion of the nursery in all probability is the simplest solution of this problem. Considered as increasing degrees of dispersion and safety are (1) cubicle units each completely equipped; (2) nurseries of no more than three or four beds to be closely associated with a similar number of maternal beds; (3) newborn infants housed in rooms adjacent to or in the mother's room; (4) hospital delivery and discharge within forty-eight hours, and (5) the ultimate of dispersion, frank home delivery.

4753 Broadway.

ABSTRACT OF DISCUSSION

DR. ERNEST WOLFF, San Francisco: The problem which Dr. Spivek has discussed still gives a headache to pediatricians and obstetricians alike. Not only do epidemiologists criticize the hospital nursery but psychiatrists today are objecting to the psychologic hazards of separating mother from child in an artificial hospital situation. Nevertheless, in a modern city the hazards and awkwardness of home delivery in most instances far outweigh any danger from a well conducted nursery. I think that, with a well thought out routine, epidemics of the newborn are preventable. Of the suggestions which Dr. Spivek makes, there are objections to several. If nurseries of three or four beds are closely associated with maternal beds, and if the same nursing force takes care of mothers and children, there is a possibility of carrying infection from lochia to baby. Concerning individual units, one hospital in San Francisco is actually set up to house each child in the same room or a room adjacent to the mother. This requires a special nurse for each, mother and child, and increases the expense. If the conclusion is reached that the hospital nursery is, after all, the most practical solution, one must emphasize the essential factors in good routine, which, as Dr. Spivek points out, must be based on completely equipped and separately run baby cubicles. I want to say something about the experiences we had in Mount Zion Hospital, San Francisco, covering a period of six years. The details have been demonstrated in the exhibit. The most important aspect of the routine has been the development of a truly cooperative spirit, in addition to a rigid technic, a spirit which unites house staff, nurses and physicians and which is carried out in such a friendly way that parents and relatives gladly share in the protection of their own baby as well as all others. Isolated cases of impetigo may occur under the best routine, but I think that an increased number of infected babies is always due to break in routine, and it is easily detectable. Critical evaluation of practices which have become conventional, such as Dr. Spivek has made in his paper, are very important. Only by such appraisal can practice be kept up with new experience.

DR. L. HOWARD SMITH, Portland, Ore.: As I understand Dr. Spivek's paper, he is not primarily interested in the prevention of the cutaneous infections of the newborn but epidemic diarrhea of the newborn. To see one of these infants literally wither before one's eyes is terrifying. Dr. Spivek is presenting a method to stop the spread of fatal diarrhea of the newborn. Until more concerning its etiology is known, there will be difficulty in stopping its entrance into the nursery. Once it has arrived, good nursing technic has not stopped its spread to other babies. Dr. Spivek speaks of the normal flow of traffic

in the nursery for newborn infants. This traffic has been lessened by the method of not bathing and nonoiling the newborn. The time spent each day by the nurse hovering over the baby is greatly lessened. In the average charity hospital or county hospital, where the infant population varies from eighteen to fifty a day, suggestions 1, 2 and 3 are hardly practical, but hospital delivery and discharge within two to three days would seem highly desirable. This practice has been carried out in certain hospitals with excellent results. Of course, the ultimate of dispersion is home delivery, but I cannot picture an obstetrician with a trailer hitched to his car carrying delivery equipment going out to deliver a baby in the home. Dr. Spivek deserves a medal from the Section on Pediatrics for suggesting such a practical method.

DR. MAURICE L. BLATT, Chicago, Ill.: Dr. Spivek's subject is most timely in view of the fact that epidemics of sepsis have invaded the nurseries for the newborn of institutions from New York to the Pacific. San Francisco apparently has been fortunate in not having had a serious epidemic in any of its nurseries. The problem as presented by Dr. Spivek is a result of our type of civilization. The assembling of large groups of people in a single hospital endangers each by intimate contact with carriers or individuals with disease. To disassemble such a civilization is difficult and it is this which Dr. Spivek suggests. I do not believe that advance can be made along the lines so suggested. I believe it is up to us as scientists, as pediatricians, as research workers, to determine a more effective method of prevention of sepsis in the newborn in nurseries in large communities. Nurseries will continue to be large because in no other way can we finance the care of the large number of indigent and semi-indigent patients thrust upon us.

DR. M. K. WYLDER, Albuquerque, N. M.: I come from a state where 40 per cent of the population live long distances from a doctor, where about 30 per cent of our women are delivered not even by a physician, and over 50 per cent of the women in our state are delivered in the homes. I see a great many of these babies that are delivered by a dirty Mexican midwife who washes her hands after the delivery instead of before it. However, in cases in which delivery is done on a sheep pelt laid under the woman in the bed, impetigo and septic infections do not result. While I don't think any of us want to go back to home delivery, impetigo and septic infections in the newborn in the home delivery aren't seen by us. This, then, is purely a problem for the hospital. As Dr. Arthur Abt told the round table at Delmonte the other day, if the hospitals don't solve these problems, the deliveries will go back to the home again. I believe the hospitals will solve them.

DR. IRVING J. WOLMAN, Philadelphia: I think all pediatricians who are familiar with the problems of the nursery would agree with Dr. Spivek whole-heartedly. One big problem, of course, lies in the etiology of these gastrointestinal infections which are now making their appearance all over the country. We younger men wonder whether these epidemics are new things or whether they have been going on for years without being reported in the literature. Most hospital routines are based on the assumption that the infective agents spread by direct contact and fomites. A most important but hitherto neglected approach lies in the prevention of air borne infections by the newer methods of air hygiene. It is questionable whether restricting the number of infants in any one nursery to two or four is sufficient. It would be better to isolate each individually. There are some new developments in the form of air conditioned cubicles within which infants are completely protected and isolated from the outside world. Dr. Chapple of Philadelphia presented a description of one such chamber before the American Pediatric Society last month. His rigid isolation technic includes the breathing of air from outdoors where the bacterial count is very low. The addition of atmospheric sterilization to the nursery armamentarium may prove of service in the control of nursery epidemics.

DR. MANDEL S. SPIVEK, Chicago: This paper is a theoretical one, a paper which was gotten up at a desk. It has nothing to do with research or with a reading of literature. It is my own appraisal of what goes on in the nursery. Dr. Wolff has

a wonderful setup at the hospital with which he is associated, in which one of the most important things is the *esprit de corps*. That is, every one is aware of the technic, every one is conscious of it. There are very few hospitals that have that mutual understanding. Under those conditions, the spread of infection is difficult. Whether we can go back to home delivery or not, I do not know. It took a lot of educating and a lot of pushing to get the mothers from the home into the hospital. It will take the same education and the same push to get them back to their homes for delivery. It is merely a matter of education. It should not be difficult; I don't see any reason why we can't. Dr. Wolman spoke of air borne infection. We really do not know whether it is air borne or not or whether it is a virus disease or not. Various organisms have been reported, and in a thorough search for the virus in the Chicago epidemic nothing was found.

SODIUM DIPHENYL HYDANTOINATE IN THE TREATMENT OF CON- VULSIVE DISORDERS

H. HOUSTON MERRITT, M.D.

AND

TRACY J. PUTNAM, M.D.

BOSTON

Good results in the treatment of patients with convulsive seizures have been obtained by a variety of methods, such as medical treatment with bromides or barbituric acid compounds, the ketogenic diet, restriction of fluids, and the surgical excision of scars or irritable cortical foci. In spite of these various therapeutic means there are a great number of patients who are not relieved of their attacks or are helped only temporarily by treatment. The fact that treatment by anticonvulsant drugs is at present the most widely used and on the whole the most effective method of therapy suggested to us the possibility that a direct and systematic experimental search might reveal more potent and less sedative compounds. With this idea in mind we devised an experimental procedure¹ which would produce convulsive

Chemical structure of sodium diphenyl hydantoinate.

seizures in animals at a constant threshold and which would allow for a qualitative and roughly quantitative determination of the relative effectiveness of various drugs. By this method a large number of chemicals and drugs, selected on theoretic grounds, were studied, and it was found² that several heretofore unused chemicals were as effective in protecting animals from the electrically induced convulsions as the drugs commonly used in the treatment of patients with convulsions (bromides, phenobarbital and the like) or even more effective.

Under the auspices of the Harvard Epilepsy Commission. This study was aided by a grant from Parke, Davis & Co., Detroit. From the Neurological Unit, Boston City Hospital, and the Department of Neurology, Harvard Medical School.

Read before the Section on Nervous and Mental Diseases at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 17, 1938.

1. Putnam, T. J., and Merritt, H. H.: Experimental Determination of the Anticonvulsant Properties of Some Phenyl Derivatives, *Science* 85: 525-526 (May 28) 1937.

2. Merritt, H. H.; Putnam, T. J., and Schwab, D. H.: A New Series of Anticonvulsant Drugs Tested by Experiments on Animals, *Arch. Neurol. & Psychiat.* 39: 1003 (May) 1938.

One of these chemicals, sodium diphenyl hydantoinate, which was especially effective in protecting animals from electrically induced convulsive seizures with little sedative effect, was subjected to extensive pharmacologic and toxicologic tests by Krayner and by Kamm and Gruzhit.³ The results of these tests showed that it was well tolerated by the ordinary laboratory animals (cats, dogs, rats) in massive single and long-continued daily doses. It was therefore considered safe to make a trial study of the drug in patients suffering from repeated convulsive seizures.

Sodium diphenyl hydantoinate is somewhat analogous in structure to the barbiturates, being a derivative of glycolyl urea rather than of malonyl urea. It is an odorless white powder with a bitter taste; it is soluble in water, slightly soluble in alcohol and insoluble in benzene and ether. The aqueous solution is alkaline to litmus and shows a p_H of 11.7.

In order to determine the relative effectiveness of this drug on convulsive disorders in human beings, a group of patients was selected who had been having frequent convulsive seizures for many years and who had obtained little or no benefit from the usually accepted treatment, i. e. bromides, phenobarbital, ketogenic diet, restricted fluid intake and the like. The vast majority of these patients would be classified as having severe epilepsy.

CLINICAL RESULTS

At the time of the preparation of this report, the medicine has been administered to 200 patients for a period varying from three weeks to eleven months. The results reported in this study are those in 142 patients with frequent attacks who have received the treatment for a period greater than two months, varying from extremes of eleven and two months, with an average of 4.3 months.

In Patients with "Grand Mal" Seizures.—Of the 118 patients with frequent grand mal attacks, complete relief of attacks has been secured in sixty-eight (58 per cent) and a marked reduction in the number of attacks in an additional thirty-two (27 per cent). In eighteen (15 per cent) there was only a moderate degree of improvement or no improvement over the previous status with bromides or phenobarbital therapy.

The results are shown in table 1 and two illustrative case histories are given here:

CASE 1.—B. H., highschool boy aged 15, white, with a history of one grand mal attack in infancy, began at the age of 11 years to have mild grand mal attacks with loss of consciousness for from two to four minutes. These attacks occurred three or four times a week for the first year and neither their frequency nor their severity were reduced by treatment with bromides or phenobarbital. At the age of 12 there was a spontaneous remission for one year. The attacks recurred at the age of 13 at daily intervals and were not influenced by phenobarbital or methyl ethyl phenobarbital (mebaral). The physical and mental development was normal and the neurologic examination gave negative results; the blood, urine and cerebrospinal fluid were normal. Roentgenograms of the skull were negative. Electro-encephalography showed evidences of abnormal cortical activity, with frequent short bursts of abnormal waves of the grand mal and psychomotor types described by Gibbs and Lennox.⁴

Treatment was started Sept. 15, 1937, with 0.1 Gm. of sodium diphenyl hydantoinate three times a day. There was complete freedom from attacks until May 1, 1938, when attend-

ing a dance while visiting friends he forgot to take his medicine and had two grand mal attacks in bed the next day.

Examinations of the blood and urine on several occasions since the start of treatment have shown no abnormalities.

CASE 2.—A. W., a white man, aged 26, suffered from severe grand mal attacks of five years' duration, occurring almost daily with an increase in frequency to two or three attacks daily during the month before entry to the hospital, although the patient was receiving 6 grains (0.4 Gm.) of phenobarbital daily. Examination was negative except for bilateral middle ear deafness and mental deterioration (mental age 9). The blood, urine and spinal fluid were normal. Roentgenograms of the skull were negative. Electro-encephalography showed frequent bursts of abnormal cortical activity of the grand mal type.⁴

Treatment was started Dec. 2, 1937, with 0.1 Gm. of sodium diphenyl hydantoinate three times a day. The patient has been entirely free of attacks since starting treatment.

In Patients with "Petit Mal" Seizures.—In seventy-four patients with frequent petit mal attacks, complete relief was obtained in twenty-six (35 per cent) and a marked reduction in the number of attacks in thirty-six (49 per cent). In twelve (16 per cent) there was only slight or no improvement over the status under

TABLE 1.—Effect of Sodium Diphenyl Hydantoinate on Grand Mal Convulsive Seizures in 118 Patients with Frequent Attacks Who Have Been Treated for a Period Greater Than Two Months

Completely relieved.....	29	35	4	68	58
Greatly decreased.....	14	17	1	32	27
Moderately decreased.....	6	0	0	6	5
No change.....	10	2	0	12	10
Total.....	59	54	5	118	100

previous forms of therapy. It will be noted from a study of table 2 that the percentage of relief or great reduction in the petit mal attacks was highest in the patients in whom the petit mal attacks were associated with those of the grand mal type. Two illustrative histories are given here:

CASE 3.—D. R., a graduate nurse, aged 22, began to have petit mal attacks two and one-half years before examination. These were characterized by blinking of the eyes and a momentary lapse of consciousness without falling. Attacks occurred from one to three times a day.

The physical and neurologic examinations were negative and the blood, urine and spinal fluid were normal. Roentgenograms of the skull were negative. Electro-encephalograms showed disturbance of the cortical activity typical of petit mal.⁴

Treatment was started Oct. 22, 1937, 0.1 Gm. of sodium diphenyl hydantoinate being administered three times a day, with complete relief of attacks. The patient has attempted to go without the medicine on several occasions since with return of attacks.

CASE 4.—H. D., a white youth, aged 19, had been suffering for the past ten years with nocturnal grand mal attacks occurring two or three times a month and petit mal attacks several times a day. Previous treatment with phenobarbital (3 grains [0.2 Gm.] daily) had not reduced the frequency or severity of the attacks. The physical and neurologic examinations were negative. Examination of the blood, urine and spinal fluid was negative.

Treatment with sodium diphenyl hydantoinate 0.2 Gm. at bedtime was started Dec. 10, 1937. Since this date there has been complete relief from the petit mal attacks, but grand mal attacks occurred on December 17 and 28. The dosage

3. Personal communications to the authors.

4. Gibbs, F. A.; Gibbs, E. L., and Lennox, W. G.: Cerebral Dysrhythmias of Epilepsy, Arch. Neurol. & Psychiat. 39:298 (Feb.) 1938.

of sodium diphenyl hydantoinate was increased to 0.4 Gm. daily on December 29. Grand mal attacks occurred on January 30 and March 20. The dosage was then increased to 0.6 Gm. daily with freedom from all attacks since March 20.

In "Psychomotor Equivalent" Attacks.—Of the six patients with psychomotor equivalent attacks there has been complete relief in four (67 per cent) and a very marked reduction in the frequency of attacks in two (33 per cent). The results are shown in table 3 and two illustrative cases are given here.

CASE 5.—S. B. R., a white man, aged 54, an insurance salesman, gave a history of attacks of five years' duration, occurring two or three times a day, characterized by a turning of the head to one side, chewing movements of the jaw, mental cloudiness and performance of automatic actions, such as taking off shoes. The patient would not fall but would be unable to answer questions or talk coherently for from thirty to ninety seconds.

The physical and neurologic examinations were negative. The blood, urine and spinal fluid were normal and roentgenograms of the skull were negative. Electro-encephalography showed evidences of abnormal cortical activity typical of those found in patients with psychomotor equivalents.⁴

Previous treatment had consisted of 9 grains (0.6 Gm.) of phenobarbital and 30 grains (2 Gm.) of sodium bromide daily, plus calcium gluconate, with no effect on the severity or frequency of the attacks. The patient was started on treatment with sodium diphenyl hydantoinate Aug. 8, 1937, in doses of from 0.4 to 0.6 Gm. a day. The frequency of attacks has decreased from two or three attacks daily to an average of three attacks a month.

CASE 6.—S. H. R., a man aged 55, an unemployed salesman, had attacks which started at the age of 15 with a transient feeling of nausea and blinking of the eyes. These occurred at irregular intervals for seven years. At the age of 22 he had grand mal attacks at night for a period of eight years, after which the grand mal attacks ceased and the petit mal attacks passed over into psychic equivalents. In these attacks he would perform automatic movements and talk and answer questions, but he would not remember what had happened afterward. These attacks occurred from three to five times a week. An attack would last from one and one-half to three minutes, followed by a period of mental cloudiness for from five to ten minutes.

TABLE 2.—Effect of Sodium Diphenyl Hydantoinate on Petit Mal Convulsive Seizures in Seventy-Four Patients with Frequent Attacks Who Have Been Treated for a Period Greater Than Two Months

Completely relieved.....	6	20	26	35
Greatly decreased.....	7	29	36	49
Moderately decreased.....	1	2	3	4
No change.....	6	3	9	12
Total.....	20	54	74	100

General physical and neurologic examinations were negative. Electro-encephalography showed evidences of abnormal cortical activity. Previous treatment had been from 1½ to 3 grains (0.1 to 0.2 Gm.) of phenobarbital a day.

The patient was started on treatment March 18, 1938, with 0.4 Gm. of sodium diphenyl hydantoinate a day. There was complete relief from attacks until April 3, when the patient complained of extreme nervousness and shaking of the hands. The dose of medicine was decreased to 0.2 Gm. daily on April 3 with relief of the nervousness but with return of attacks. April 14 the dose was increased to 0.3 Gm. a day with complete relief of attacks since but with the occurrence of anorexia and a feeling of nausea without vomiting. This has

been relieved by taking the medicine with his meals. Examinations of blood and urine since treatment was started have shown no abnormality.

DOSAGE

The dose used for adults varied between 0.2 and 0.6 Gm. a day, depending on the therapeutic effect and toxic reactions. As a rule adult patients were started on a dose of 0.1 Gm. three times a day, increased up to a maximum of 0.2 Gm. three times a day if therapeutic effects were not obtained. Small children were started on 0.1 Gm. twice a day, increased up to 0.4 or 0.5 Gm. daily until the optimum therapeutic dosage

TABLE 3.—Effect of Sodium Diphenyl Hydantoinate on Psychic Equivalent Seizures in Six Patients with Frequent Attacks Who Have Been Treated for a Period Greater Than Two Months

Frequency of Attacks	Psychic Equivalents Alone	Psychic Equivalents Associated with Grand Mal	Total	Per Cent
Completely relieved.....	0	4	4	67
Greatly decreased.....	1	1	2	33
Total.....	1	5	6	100

was determined. For convenience the medicine was usually administered at meal time. It was found that gastric symptoms were avoided by the few patients in whom they occurred by taking the medicine along with or after the meal rather than before it. The dose in the seventy-two patients who were relieved of their attacks varied from 0.2 to 0.6 Gm. with an average of 3.6 Gm. Relief was obtained on a dose of 0.3 Gm. a day by forty-two patients. In contrast, the average dose for the forty-five patients in whom the attacks were greatly decreased in frequency was 4.3 Gm. and for the unimproved group the average dose was 4.6 Gm. Although 0.6 Gm. was considered to be the maximum therapeutic dose, the average dose in the group of cases in which treatment was not effective was only 0.46 Gm. This is explained by the fact that many of the patients in the latter group were not able to take larger doses owing to the appearance of minor toxic symptoms, such as tremors, ataxia, diplopia or dizziness.

TOXIC REACTIONS

The toxic reactions can be divided into two groups:

1. Minor toxic symptoms such as dizziness, ataxia, tremors, blurring of vision, diplopia and slight nausea. This type of reaction occurred in approximately 15 per cent of the patients. They tended to occur between the third and the tenth day of treatment and could be relieved by reducing the dosage. If the reduced dosage was not effective in controlling the seizure, it could in most instances be increased after a few days without the return of symptoms. In a few cases the dose could not be maintained at the optimum level of effectiveness on account of the appearance of these symptoms whenever attempts were made to increase the daily dose to more than 0.4 Gm.

2. More serious toxic reactions in the nature of dermatitis and purpura. Dermatitis occurred in ten cases (5 per cent) but in only one instance was the dermatitis considered to be of a serious nature. This was in a man, aged 55, in whom an exfoliative dermatitis developed forty days after he started the treatment.

The medication was immediately discontinued and the dermatitis gradually cleared. A brief abstract of his record is given:

CASE 7.—C. E., a man, aged 55, unmarried, a postoffice employee, was seen in 1933 with a history of grand mal convulsive seizures two or three times a month for two years. Complete physical and neurologic examinations at that time, including roentgenograms of the skull and examination of the spinal fluid, were negative except for a moderate degree of hypertension; the blood pressure was 140 systolic, 106 diastolic. He was discharged to his local physician and treated with phenobarbital and bromides with a temporary decrease in the frequency of the attacks, but they gradually recurred with their former frequency. Sodium diphenyl hydantoinate in a dose of 0.1 Gm. three times a day was started March 7, 1938. The patient's blood pressure at this time was 205 systolic, 130 diastolic. A convulsion occurred March 21 and the dose was increased to 0.1 Gm. four times a day. April 15 a morbilliform rash appeared on the face, trunk and extremities and developed into a brawny red maculopapular rash. There was no fever and, with the exception of a mild degree of itching sensation in the skin, the patient had no symptoms. He was admitted to the hospital, where he remained for approximately three weeks. The rash gradually cleared up, white wash being used to relieve the itching. In the hospital, examinations of the blood and urine were negative. The kidney function test showed a phenolphthalein excretion of 55 per cent in two hours. With the withdrawal of sodium diphenyl hydantoinate there was immediate return of convulsive seizures. These were controlled with large doses (6 grains [0.4 Gm.] a day) of phenobarbital.

In the remaining nine cases the cutaneous reactions were of erythematous, scarlatiniform or morbilliform nature. This type of reaction usually occurred on the ninth to the tenth day of treatment and was frequently accompanied by fever. The rash disappeared in all patients regardless of whether the treatment was discontinued. In seven of the nine patients the treatment was interrupted by us as soon as a rash was reported. Two patients failed to report the rash and continued to take the medicine throughout the period of duration of the rash. Five of the seven patients in whom the use of the medicine was discontinued during the period of the rash were put back on the treatment after a few days, since the medication had been effective in relieving the attacks. Treatment was discontinued in the two patients who had not been relieved of the attacks. In another patient treatment has not been resumed, although it had been effective, since we desired to observe the patient in the hospital when further treatment was instituted.

Two examples of cutaneous reactions are given:

CASE 8.—G. G., a high school girl aged 13, began to have petit and grand mal attacks at the age of 2½ years. The petit mal attacks occurred several times a day and the grand mal attacks every three or four days. Previous treatment with the ketogenic diet, bromides and phenobarbital were ineffective. The physical and mental development was normal. Physical examination and examinations of the blood, urine and spinal fluid were negative. Roentgenograms of the skull were negative. Treatment with sodium diphenyl hydantoinate 0.1 Gm. three times a day was started Jan. 28, 1938. February 7 (ten days after treatment was started) a generalized scarlatiniform rash appeared accompanied by a fever of 102 F. The treatment was discontinued and the rash and fever disappeared in four days. Treatment was reinstituted four days after the disappearance of the rash in a dose of 0.2 Gm. daily. Grand mal attacks occurred on February 18 and 19. The dosage was increased to 0.3 Gm. daily with no attacks until March 10. On a dosage of 0.4 Gm. a day the patient has been free of attacks since March 10. The blood and urine on several occasions since treatment was started have been normal.

CASE 9.—M. P., a white boy aged 13 years, had had left jacksonian convulsive attacks since the age of 1 year. The third attack at the age of 3 was followed by a left hemiplegia, which has persisted. The frequency of the attacks gradually increased and for the past few years they occurred on the average of five or six times a day. An attack was characterized by convulsive movements of the left arm and leg, lasting from thirty seconds to five minutes without loss of consciousness. Previous treatment had consisted of large doses of phenobarbital, bromides and "donhide," a proprietary preparation containing bromides and extract of scutellaria, without any appreciable effect on the frequency or severity of the attacks. On examination there was a spastic left hemiparesis and a moderate degree of mental retardation.

Treatment with sodium diphenyl hydantoinate 0.1 Gm. three times a day was started Jan. 24, 1938. After five days of treatment there was no change in the frequency of attacks and the dose was increased to 0.5 Gm. daily with complete relief from the attacks. February 2, nine days after the institution of treatment, the patient complained of itching of the legs and hands, and a faint scarlatiniform rash developed over the face and extremities. Treatment was discontinued and there was a prompt return of the attacks. The rash and fever disappeared by February 7 and the sodium diphenyl hydantoinate was started again in doses of 0.1 Gm. daily. This was increased to 0.3 Gm. February 17, and since then attacks have been very mild and very infrequent, permitting the boy to attend school. Frequent examinations of the blood and urine since the treatment was started have shown nothing abnormal.

In one case purpuric lesions developed on the buttocks approximately two months after the treatment was started. The patient had been relieved of his attacks. Since there were no constitutional symptoms and a thorough study of the blood was negative, and since the lesions were beginning to clear before the patient reported them, treatment was not interrupted. A brief abstract of this case is given here:

CASE 10.—K. C., a white man, aged 35, a machinist, had had convulsive seizures three years before entry to the hospital. These occurred occasionally in the day time but were more frequent at night, occurring from seven to eight times each night. They were characterized by an aura of belching and choking sensation and the occurrence of slight convulsive movements of the arm and invariable incontinence of urine. The attacks would last for from thirty to ninety seconds. In addition, the patient had had five grand mal seizures. General physical and neurologic examinations were negative. Studies of the blood and urine were negative and roentgenograms of the skull were negative. Electro-encephalograms showed abnormal waves of the grand mal and psychomotor types.⁴ The patient was started on treatment Dec. 7, 1937. For the first three weeks of treatment there was no decrease in the frequency of the attacks, but the urinary incontinence which had previously accompanied the attacks disappeared. After this there was a gradual decrease in the frequency of the attacks so that by the second month of treatment they occurred only two or three times a week and by the tenth week they had disappeared entirely. February 15, approximately eleven weeks after the treatment was started, the patient had some teeth extracted under procaine hydrochloride anesthesia. February 19, large ecchymotic lesions were noticed on the buttocks by the patient's wife. Since the attacks had ceased the patient had discontinued the medicine February 18, but when they began to recur on February 22 he resumed the use of the medicine. The presence of the lesions was not reported to us until March 7, as the patient had attached no significance to them. At that time they were large brownish areas on both buttocks. The hemoglobin content of his blood was 88 per cent, red blood cell count 4,800,000 and white blood cell count 14,200, with 78 per cent polymorphonuclears, 19 per cent small lymphocytes, 2 per cent large lymphocytes, 1 per cent eosinophils. The red blood cells and platelets appeared normal in smear and the platelet count was 322,000 per cubic millimeter. The bleeding time was one and one-half minutes and the tourniquet test was negative. The blood was reexamined care-

fully ten days later with no change in the red blood count or hemoglobin content. The white blood count was 10,000 with differential count as before; the platelet count was 337,000; bleeding time two minutes, icteric index 5. The patient has been continued on treatment since with no return of attacks. There have been no new lesions, and the lesions on the buttocks have gradually faded. Frequent examinations of the blood and urine have shown no abnormality.

COMMENT

The results here reported indicate that sodium diphenyl hydantoinate was effective in controlling convulsive seizures in a great majority of a selected group of patients who were not helped by other methods of therapy. It is natural to assume, therefore, that even more satisfactory results could be obtained in patients with a less severe tendency to convulsions.

It must be noted that with a few exceptions the duration of treatment in the majority of the cases was less than six months. It is probable, therefore, that many of the patients in the "completely relieved" group will later be transferred to the other groups, but it is also possible that greater experience with the use of the drug will make it possible to obtain better results in some of the cases in the moderately or greatly improved groups. Whether or not some of the patients will ultimately become refractory to this treatment, as has occurred with other forms of therapy, remains to be seen.

In addition to a relief or a great reduction in the frequency of the attacks, it was frequently noted by the parents of children that they were much better behaved, more amenable to discipline and did better work in school. This improvement must have been due in great part to the freedom from attacks, but it is also possible that the medication produced other changes in the activity of the cerebral cortex. Studies of the cortical activity by means of the electro-encephalogram before and after treatment with sodium diphenyl hydantoinate are being conducted in collaboration with Dr. F. A. Gibbs and will be reported at a later date. The results of this study may conceivably lead to the use of the drug in conditions other than the convulsive state associated with similar cortical dysrhythmias.⁴

Sodium diphenyl hydantoinate has been shown to be a relatively nontoxic drug when given in doses of from 0.2 to 0.6 Gm. a day. There were no fatalities in a group of 200 patients and in only two patients was there a reaction that could be considered as serious in nature—an exfoliative dermatitis in one patient and a nonthrombocytopenic purpura in the second. Frequent studies of the blood and urine failed to reveal any evidence of damage to the hemopoietic system or kidneys in any of the 200 patients. The toxic dermatitis produced by the drug, with the one exception already noted, was of a benign nature and was quite similar to that produced by another hydantoin compound, phenylethyl hydantoin (nirvanol), which was formerly used in the treatment of chorea minor. Sodium diphenyl hydantoinate is without doubt, however, considerably more toxic than bromides and the barbituric acid compounds. Cutaneous reactions as well as the minor toxic symptoms of tremors, ataxia, diplopia, dizziness and the like are much more frequently encountered. The high degree of alkalinity of the drug sometimes causes a sensation of nausea and discomfort in the abdomen, making it difficult for some patients to take it regularly. It is possible also that a more extensive use of the drug will result in other toxic reactions which we have not

as yet encountered in our 200 patients. In spite of these handicaps we feel that sodium diphenyl hydantoinate is a valuable addition to the medical armamentarium in the battle against epilepsy and that it is worth trying with proper precautions in patients who have not responded to the less toxic modes of therapy, such as the bromides, the barbituric acid compounds or the ketogenic diet.

The optimum dosage of the drug must be determined by trial. Children above the age of 6 and adults should be started on a dose of 0.1 Gm. three times a day. Gastric discomfort and nausea can usually be prevented by giving the capsule with or immediately following the meals. If seizures are not controlled by the end of from seven to ten days an additional dose should be given at bedtime. Further increase in the dose, up to a maximum of 0.6 Gm. a day, can be adjusted according to the tolerance of the patient. Infants and children up to the age of 5 years should be started on a dose of from 0.1 to 0.2 Gm. a day, which can be gradually increased to 0.3 to 0.4 Gm. a day if necessary.

The appearance of minor toxic symptoms, such as nervousness, tremors or ataxia, calls for a reduction in the size of the dose. If the reduced dose is ineffective, attempts can be made after from five to ten days to increase it. The use of the drug should be immediately discontinued if more serious toxic symptoms, dermatitis, purpura and the like develop. An exfoliative dermatitis makes further use of the drug absolutely contraindicated. A mild erythematous, morbilliform or scarlatiniform reaction occurring on the eighth to the eleventh day of treatment is not of such serious import, and, if there are definite indications that the drug has been effective in relieving severe attacks, it can be given again in small doses with caution. If no untoward symptoms develop, the dose can be increased gradually every four to six days. On the reappearance of any toxic manifestation, further use of the drug is prohibited.

If patients have been receiving large doses of bromides or phenobarbital, these should be continued along with the sodium diphenyl hydantoinate, the dose of the bromides or phenobarbital being gradually decreased over a period of from four to seven days. This is advisable since the sudden withdrawal of the bromides or phenobarbital may result in the precipitation of a series of attacks before a reservoir of sodium diphenyl hydantoinate has been built up.

Our experience with the drug has not been sufficient to determine all the contraindications for its use. At present we feel that it should not be given to elderly persons with hypertension or other evidences of cardiovascular disease, or to debilitated patients.

SUMMARY

1. In a previous study it has been shown that sodium diphenyl hydantoinate is effective in preventing electrically induced convulsive seizures in cats. The drug is relatively nontoxic and well tolerated by the usual laboratory animals.

2. A clinical trial of sodium diphenyl hydantoinate was made in 200 patients with frequent convulsive seizures which had not been relieved by the previous modes of therapy.

3. In 142 such patients who have received the treatment for periods varying from two to eleven months, grand mal attacks were relieved in 58 per cent and greatly decreased in frequency in an additional 27 per

cent; petit mal attacks were relieved in 35 per cent and greatly decreased in frequency in an additional 49 per cent, and psychic equivalent attacks were relieved in 67 per cent and greatly decreased in frequency in 33 per cent.

4. There were no fatalities. A toxic dermatitis occurred in ten patients (5 per cent), nonthrombocytopenic purpura in one patient and minor (in many instances, transient) toxic reactions, tremors, ataxia, dizziness and the like in approximately 15 per cent.

CONCLUSIONS

Sodium diphenyl hydantoinate is a valuable addition to the physician's armamentarium in the battle against "epilepsy." Its use should be restricted, for the present, to that group of patients who do not respond to the less toxic forms of therapy previously in common use.

818 Harrison Avenue.

ABSTRACT OF DISCUSSION

DR. EUGENE ZISKIND, Los Angeles: The discovery of this drug is an indication of the mental alertness of these authors, which has been shown in much of their previous experimental work. The discovery is based on attention to a clinical observation with which some physicians may not be acquainted. Drs. Merritt and Putnam observed that whereas phenobarbital controls seizures in a high proportion of cases that is not true of other barbiturates, and so, concentrating on the phenol fraction of the phenobarbital, their investigation led to the trial with these various drugs which showed so definite an effect on the convulsive seizures. In epilepsy, therapy of this type is essential for long periods, often many years. I would be interested in seeing what the incidence of complication is when this drug is used for longer periods. The statistical results so far reported are far in excess of what one would expect as a chance of variation. Dr. Somerfeld and I had occasion to observe that phenobarbital markedly increased the extrapyramidal rigidity in cases of parkinsonism, and we shall be stimulated by this study to investigate also whether or not the response there has been from barbiturates or by the phenol elements. We are also looking forward to an opportunity to use this drug, which appears to be a notable advance in the therapy of convulsive disorders.

DR. T. J. PUTNAM, Boston: The results of the use of this drug, as reported by the authors and by Dr. Shurly from Dr. Kimball's clinic, speak for themselves. I should like to emphasize in relation to this project, however, not alone the efficacy of this drug but the fact that, it seems, a new method of studying modes of therapy of convulsions has become available. There probably are several kinds of convulsions. Perhaps there should be several types of medication to control them. This is only one drug found through a preliminary experimental survey. There is reason to believe there are perhaps many others and maybe more effective ones still to be found.

The Health of Early English Queens.—Henry VIII had studied pharmacy and often mixed medicines in his own laboratory as a pastime between his six love affairs; but his medical knowledge did not extend to obstetrics. His Queen Catherine in eight pregnancies had only one living child. Anne Boleyn had but one living child, the future queen Elizabeth, and two miscarriages. Jane Seymour died of fever soon after her son, Edward VI, was born. He died at the age of 16. Queen Mary, Catherine's daughter, was more concerned with her own health and the combating of heresy than the health of her people. Queen Elizabeth, who had been sickly from her eleventh year, had to submit to so many bleedings and purgings that it is a wonder that she lived to reign at all. Elizabeth was, perhaps, the most thoroughly educated woman of her age. She spoke several languages and wrote Latin and Greek easily. She had dabbled in medicine.—Hurd-Mead, Kate Campbell: *A History of Women in Medicine*, Haddam, Conn., the Haddam Press, 1938.

RECENT RESEARCHES IN NUTRITION IN RELATION TO PREVENTIVE MEDICINE

NINA SIMMONDS, Sc.D.

SAN FRANCISCO

Hippocrates is reported to have stated that "there are many other ills different from those of repletion but no less dreadful arising from deficiency of diet." The history of medicine contains many references to observations which supported the theory that there is a relationship between diet and certain diseases such as beriberi, scurvy, night blindness, osteomalacia and rickets, known by various terms in different languages.

With the advent of bacteriology and its brilliant discoveries, however, the idea that disease can be brought about by lack of something in the diet was difficult to comprehend, especially in the light of the many diseases which were shown to be of bacterial origin. It was not until the fundamentals of an adequate diet were demonstrated by means of animal experiments that a relationship between faulty diet and the so-called deficiency diseases could be demonstrated. Pernicious anemia, diabetes and goiter will not be discussed in this paper.

With the possible exception of pellagra, clearcut clinically defined disease entities of dietary origin have not played a large part in mortality and morbidity statistics, so in the past the attention of public health officials and physicians interested in preventive medicine has not been focused on the role of nutrition in the public health program. However, it is now recognized by many physicians, nurses, nutritionists and others interested in the public welfare that malnutrition and borderline deficiency diseases are not uncommon in the low income groups and also among persons with sufficient incomes but with faulty food habits. Malnutrition has been spoken of as "the great disease of the American school child."

There is an interesting history of nutrition which laid the foundation for much of the recent work, but, fundamental as were the studies of the early investigators on the mineral, energy and protein needs of the body, it was not until about 1925 that there existed a practical working knowledge of the subject. The development of the newer knowledge of nutrition may be said to have begun about the end of 1915. From about 1912 on the vitamin hypothesis was in the air. It was inevitable that soon some of the various investigators working in the fields of biochemistry and nutrition would formulate on the basis of definite experimental evidence a working hypothesis concerning the essentials of an adequate diet. McCollum and Davis¹ did this in 1915. They stated that "in addition to the well recognized dietary factors, two as yet unidentified dietary essentials are necessary in the diet."

Many important papers published between 1915 and 1938 elaborated on this hypothesis. It is apparent to every one interested in medicine and related fields that more progress has been made in the science of nutrition since 1915 than in all time previous. Without question this has been due to the demonstration of the existence

From the Medical Center, University of California.

of the vitamins. The excellent series of articles on these factors appearing in the current issues of *THE JOURNAL* present data far beyond the fondest dreams of the biochemists of twenty-five years ago.

But what is the practical application of this research to preventive medicine and to public health? Dr. James M. Gamble² of Harvard Medical School expressed one example of a practical application when he said:

This splendid significance of the results of recent studies on rickets is not in the least subtracted from by admitting that the knowledge thus gained is not new knowledge. That cod liver oil would cure rickets has been known for several hundreds of years. This discovery is credited to fisher folk of northern Europe. That sunlight is preventive was convincingly evident to students of rickets generations ago. In recent times, however, the introduction into medicine of a commendably cautious reliance only on demonstrable data has produced perhaps a too inclusive disrespect for the older empirically established beliefs. A splendid clearance of rubbish has been accomplished, but, inevitably, grains of gold have been lost with the dross. To an even mildly critical attitude of mind the belief that oil from the liver of cod fish is specifically curative of a human ailment was obviously a quaint bit of archaic medical lore. The theory of a relationship of sunlight to prevention seemed an interesting but intangible surmise. The scientific method of thinking having produced skepticism, it was quite necessary that the rickets-preventive action of cod liver oil and of sunlight be rediscovered in irreproachably scientific terms. That this has been most beautifully done ensures a permanent and active belief in the efficacy of these agencies. And since their employment is so easily practicable we may now regard rickets as a preventable and unnecessary disease.

Another example in point: Over twenty years ago Dr. Joseph Goldberger³ of the United States Public Health Service and Dr. Beverly R. Tucker⁴ of Richmond, Va., were among the investigators who stressed the importance of an adequate diet in the treatment and prevention of pellagra. At that time, however, the vitamin content of the foods they recommended, such as meats, eggs, milk, legumes, fruits and vegetables, were not known as they are today; the language of nutrition was for the most part proteins, fats, carbohydrates, minerals, water and calories. The vitamin hypothesis was in its infancy not only in regard to the vitamin content of foods but also in relation to certain diseases. About 1913 Dr. Casimir Funk advanced the vitamin hypothesis to account for the occurrence of pellagra, beriberi, scurvy and rickets, but at that time neither the medical nor the nutritional aspects of these diseases were sufficiently advanced to make the vitamin hypothesis incontrovertible. However, as a result of research there is today at least a partial explanation of the "why" not only of the deficiency diseases but also of the part which faulty diet plays in their etiology, for there is a wealth of information on the dietary properties of foods. It is known why certain foods prevented scurvy in the past and will do so today; why pellagra did not and does not occur when milk, meats, eggs, fruits and vegetables are used in abundance; why cod liver oil and sunshine are rickets preventive. That persons may take an adequate diet and be unable to assimilate some of the factors is well known, of course, to physicians.

Furthermore, research in nutrition has made possible an analysis of racial and regional food habits. The soy bean curd of the Orient, the beans of Mexico, the poi of Hawaii, various foods of the Eskimo, including glandular organs, soft bones and blood, and the dairy products of other countries have much in common from the dietary standpoint. Human experience had demonstrated that no one food, with the exception of water, is or ever was indispensable in nutrition. Research has explained in part at least why. The following words of Dr. Woodruff⁵ are pertinent: "In ultimate analysis everything is incomprehensible, and the whole object of science is simply to reduce the fundamental incomprehensibilities to the smallest possible number."

The prevention of malnutrition and deficiency diseases is not so simple as it would first appear. According to Burnet and Aykroyd,⁶ "nutrition is an economic, agricultural, industrial and commercial problem as well as a problem in physiology." I should like to add that it is also an educational problem in which form, in the last analysis, it is probably the most difficult to handle. Beriberi still occurs in the Orient and elsewhere, pellagra is widespread, rickets is still present, a case of advanced scurvy and also of xerophthalmia occurs occasionally. Full-blown deficiency diseases are the spectacular phase of nutrition, but the prevention and also the early recognition of borderline states associated with malnutrition are of more importance from the standpoint of public health and preventive medicine. Cases of borderline deficiency are being reported with increasing frequency owing in part perhaps to better diagnosis. It is with the educational problem that the nutritionist and the public health nurse will have important roles. However, all persons adequately trained should assist with the educational program.

Owing in part to the fact that research not only has demonstrated the existence of vitamins but also has isolated and synthesized several of them, much of the world is extremely vitamin conscious at the present time. The various vitamins, dicalcium phosphate wafers and other calcium salts have been given a great deal of publicity, which has tended to focus too much attention on them. It should be emphasized that vitamin capsules, vitamin tablets and dicalcium phosphate wafers or other calcium salts are not panaceas for the solution of nutrition problems, valuable as they are or may be in supplementing certain diets. For example, the spectacular relief of the outstanding symptoms of pellagra by nicotinic acid or of scurvy by ascorbic acid does not solve the nutrition problems of patients with these diseases. Whenever possible, at least a brief nutrition history should be taken whether or not the patient shows symptoms of a deficiency disease, and if necessary the diet should be adjusted so that all dietary factors are abundantly supplied. Time, cost, convenience, likes and dislikes and habit are a few of the factors which must be taken into consideration when dietary suggestions are made. I⁷ have outlined elsewhere the procedure for taking a nutrition history.

A review of the journals devoted to biochemistry, medicine and nutrition makes one question whether there is not too much of a tendency to discuss nutrition in terms of vitamins, essential amino acids, carotene.

thiamin chloride, ascorbic acid, nicotinic acid, dicalcium phosphate, calcium gluconate, units of various vitamins in foods and units of various vitamins needed daily by the individuals. In the light of the paucity of information available twenty-five years ago, one wonders whether so far as the practical aspects of nutrition are concerned the pendulum has not swung a little too far in the direction of meticulous attention to vitamins.

Data secured from animal feeding tests and color tests and then subjected to mathematical treatment have undoubtedly a certain value in estimating the units of vitamins needed daily, but because of sources of error, which are all too numerous, should not such data be considered of relative significance instead of being discussed with such a tone of accuracy and finality? I think so.

If nutrition is going to be an important factor in the public welfare it must be viewed with perspective, as are other problems in public health. The details of vitamin research, mineral metabolism and so on are of great interest to the sciences of medicine and nutrition, but in preventive medicine and public health one must deal largely with natural foods and products made from them. Research has provided not only a wealth of information on the dietary properties of foods but also data on what changes take place during the refining, the canning, the preparation, the cooking and the storage of many foods. This information is needed when one is judging the adequacy of a food supply.

In closing, then, it may be said that the practical application of research in nutrition during the past twenty-five years has been not only to emphasize the value of sunshine and fresh air but also to give the reasons why in a system of diet the following familiar foods have unusual dietary significance: meats, including glandular organs, poultry and fish; eggs; milk in its many forms and products; fruits and vegetables (fresh, canned and frozen); legumes, and cereals and their products, especially whole grain products. Research has provided vitamin capsules, vitamin tablets, brewers' yeast tablets and numerous other vitamin preparations, many of which are excellent supplements to a diet when certain foods are disliked, but one should know what they do not contain as well as what they do contain.

Nutrition, as stated earlier, has been referred to as "an economic, agricultural, industrial and commercial problem, as well as a problem in physiology."⁴ However, because of the results of recent researches on diet and its relation to disease conditions, from the standpoint of preventive medicine and of public health, nutrition may now be considered largely a problem of economics and education.

ABSTRACT OF DISCUSSION

DR. M. J. ROSENAU, Chapel Hill, N. C.: One of the pleasures of discussing a paper is to take issue with the reader of the paper regarding facts or views. That joy is denied me because Dr. Simmonds has presented such an admirable contribution that all I am able to do is to confirm what she has said. There are certain things which may stand emphasis. In the story of the growth of knowledge of nutrition, she did not mention her own long list of notable contributions. She brought out how recent is our scientific knowledge. As a matter of fact, nutrition, while the youngest science, is the oldest in the arts. We can go back to Leviticus, in the early days of the Mosaic Code, which emphasized nutrition and the importance of selecting diet and other things with reference to it. There were two things that brought nutrition to the fore, even before these scientific contributions, and one was tuberculosis. The two

papers read today again mentioned that diet, sunshine, rest and other factors that deal fundamentally with nutrition have a bearing on the prevention and treatment of tuberculosis. That is where nutrition was taken out of playing the role of cinderella in the kitchen and taken to the ball, but she was not crowned until the vitamin discoveries. It pleased me to hear Dr. Simmonds sound a warning that on account of the novelty and brilliancy of the discoveries, progress has been so extraordinary that it has blinded us to other phases of nutrition and overemphasized the role the vitamins play. I was glad to hear her say that the place to buy vitamins is in the market, by patronizing good sunshine, and in the dairy rather than in the drug store. Taking too many vitamins that may be bought in all sorts of concentrates is about as foolish as oversalting our food. Too much of even a good thing like vitamins in certain instances is harmful. Despite what we know about nutrition, the practice lags behind the facts. Science has shown the way but it requires society to apply the facts; in other words, it becomes an economic problem, a problem in sociology; it becomes enormously complex. Another point that was clearly mentioned in the paper was that we should not place in our minds a period after any of these things about nutrition that we feel we know today. After all, the surface has only been scratched. There are many related phases of it, dealing with a norm which acts and reacts on the food we eat, depending on the air we breathe, the sunshine to which we are exposed and other things. Progress along these lines will continue, and out of this complexity will come simplicity and, in the end, a relief of one of the greatest of all burdens that mankind now suffers from; namely, malnutrition.

DR. W. A. SAWYER, Rochester, N. Y.: I am glad that Dr. Simmonds mentioned the educational feature of nutrition because for those of us having to do with employees in industry it is becoming an increasing problem; not only do we need to know what to eat but I find that workers now need to know when to eat. Commercial interests are pushing vending machines of all kinds, placing many of them in factories. Labor unions are demanding them and, as a result, we find that workers have a tendency to eat more or less continuously. Dr. Haggard, in "Diet and Physical Efficiency," states that eating five times a day is perhaps as satisfactory as eating three times a day. I should like to know whether Dr. Simmonds has any thoughts on that question.

DR. L. D. BRISTOL, New York: The place of nutrition education is well recognized, particularly in our public schools and in the field of public health, but it is only within the last few years that this subject has been recognized in industry. For the last nine years in several companies of the Bell system about 10,000 women employees have completed a twelve lesson nutrition course, a volunteer course taken out of hours, entirely on the employees' time, and we feel that such education is definitely allied to the prevention of absence because of sickness and to the increase of health and efficiency on the job. There are only a few industrial organizations at present that have nutrition specialists on their staffs. Dr. Sawyer's organization, the Eastman Kodak, is one, and our organization is another. Our classes are held in groups of about twelve, the practical work being carried on in company dining rooms and kitchens. At the end of this twelve lesson course the employee is given a certificate of graduation. I believe that more and more industrial organizations, particularly the larger companies, eventually will include nutrition education in their health education programs.

DR. NINA SIMMONDS, San Francisco: The time allotted did not permit me to discuss the practical aspects of handling an individual's nutrition problems. I have formulated a series of questions which I have called "The Nutrition History," which has proved to be of assistance in handling these problems. Any one interested may secure a copy by writing to me at the University of California, the Medical Center, San Francisco. Before discussing an individual's nutrition problems with him it is necessary to have the person keep a ten days to two weeks record of all foods eaten and the approximate amounts, including extra foods, such as candy, ice cream, milk shakes, cocktails and coca-colas. This record usually

gives a good idea of a person's present food habits and interests; it may or may not be representative of his former food habits. From this record and the answers to the questionnaire and, of course, discussing the problems with the individual, it is possible to work out a satisfactory dietary regimen. It is best to make the fewest possible changes in a person's food setup compatible with an adequate diet. Although all dietary factors may be secured from foods, because of dislikes, habits, convenience and so on, vitamin tablets and other preparations have proved valuable dietary supplements; but one should know what they do not contain as well as what they do contain. Diet and its relation to disease conditions cannot be discussed here, but The Nutrition History is also of value in handling these problems.

ALCOHOL IN RELATION TO TRAFFIC ACCIDENTS

RICHARD L. HOLCOMB, M.A.
EVANSTON, ILL.

There has been much discussion for many years of the effects of alcohol on human beings. A major question now is the effects of alcohol on the automobile driver. All too often discussions involving alcohol have been colored by emotion and have suffered from lack of facts.

Recognizing the importance of drinking to safety, I hope to define objectively and unemotionally the part alcohol plays in the accident problem. Scientific methods have lately been perfected that make such a definition possible. Through their use, it is hoped that a step forward will be taken in the solution of a serious problem.

Alcohol has long been considered an important cause of accidents. Every one will concede that it impairs the judgment and physical abilities. With the coming of the motor car, the importance of alcohol as a causative factor in accidents became increasingly apparent. Driving a motor car calls for quick thinking, rapid and coordinated operation of the controls of the car and accurate judgment. With the increase in speed of motor cars, coupled with increased congestion on highways and streets, the problem of the drinking driver has become increasingly acute.

It is the major purpose of this study to define clearly the place of the drinking driver in the present day accident problem. How much more liable is the drinking driver to be involved in an accident than the sober driver? In what percentage of accidents is alcohol a factor? In other words, an answer is sought to the questions "Are you more liable to be in an accident if you drive after drinking than if you drive not having had anything to drink? How much more liable are you?"

Most important of all is the aim to show at what concentration alcohol in the human system becomes a factor in accidents. When one encounters a person who has been drinking there is little question in one's mind as to whether or not he is under the influence of alcohol. However, when it is necessary to prove in court that he was under that influence, the problem becomes involved. Police departments have long used simple rule of thumb technics, such as observing the suspect's breath, gait, speech and condition of clothes and putting him through such tests as touching the tip of his nose

with his finger, enunciating "methodist episcopal" and writing a few short sentences from dictation to be compared later with his usual writing.

The National Safety Council's Committee on Tests for Intoxication has developed an intoxication report form¹ intended to make the most reliable use of such methods as a means of determining their dependability. This form has refined the technic of determining drunkenness from observation. It attempts to take into account and tries to get proof to rebut all the possible defenses that the person may offer, and it provides for the recording of all subjective evidence as to his condition.

The committee recognized that this method is subject to a variety of attacks by the defense because many times the condition reported could have been caused by injury or illness.² Defense attorneys make the most of this. In many cases they are able to create enough doubt as to the defendant's intoxication to secure an acquittal, especially in a jury trial. It is difficult even for a physician to take the stand and say positively from a subjective examination whether or not a person was under the influence of alcohol. It is still more difficult for the police officer to do so. While systematic, complete recording of physical symptoms of intoxication are of value, more objective tests are obviously necessary in many cases. To encourage the use of more accurate and scientific methods, the form also includes provision for chemical tests of body fluids.

Long before automobile accidents became the serious problem they now are, it was known that a relatively accurate measure of the amount of alcohol in a person's system could be made from the analysis of body fluids, as well as from the analysis of the organs themselves.

Further, an accurate correlation was found between the amounts of alcohol after absorption in the different body fluids and organs. If the amount of alcohol in one part was known, the amount in another could be accurately calculated. For convenience the amounts found in the various other fluids are related to the amount of alcohol in the blood. For example, the alcohol in the blood is 1.2 times that in the brain, 0.9 times that in the spinal fluid, 0.8 times that in the urine and 2,000 times that in the alveolar air.

When the need for such analysis was felt, certain of the body fluid tests were refined and developed. The most practical of the tests determined the alcoholic content of the spinal fluid, blood, urine, breath and saliva. There are serious objections to the first two. The spinal fluid test is dangerous because of the difficulty in drawing out a sample. Also it has the practical difficulty that it requires a physician to take the sample. The blood test has similar disadvantages to a lesser degree. Courts frown on any technic that might endanger the person examined, and there is a possible danger of infection in taking a blood sample.

Extensive developmental work has been done on tests of the urine³ and breath.⁴ They have been refined so that they now are of practical value. The saliva test

4. Harger, R. N.; Lamb, E. B., and Hulpieu, H. R.: A Rapid Chemical Test for Intoxication Employing Breath, *J. A. M. A.* 110: 779-785 (March 12) 1938.

is of proved accuracy and may come into as general use as the tests of the urine and breath.

Through urinalysis the alcohol in the blood and thus in the brain can readily and with fair accuracy be determined. It is the alcohol in the brain that affects the person, and not the gross amount drunk. Through the use of the test it is possible to tell the extent of intoxication. The Committee on Tests for Intoxication of the National Safety Council has determined the percentage of alcohol in the body fluids above which all persons will unquestionably be under its influence. A lower point has been determined that will, when coupled with supplementary evidence, serve as *prima facie* evidence of intoxication.⁵ There are two objections to the use of urinalysis for establishing intoxication. The first is the difficulty of obtaining the specimen; the person to be tested may be either unwilling or unable to cooperate. The second is that it requires the services of a technically trained person, who is not always immediately available. However, specimens may be preserved indefinitely, allowing later checks to be made by the defense as well as the prosecution.

The breath test for alcohol, while somewhat less accurate than urinalysis, has important points in its favor. In the first place, an immediate result can be obtained. Secondly, the apparatus can be operated by any intelligent person after only a short course of training. Moreover, it is a simple matter to secure a specimen of breath. Both tests are rapidly coming into use by police authorities, and their value is being proved. The saliva test is of too recent development for proper appraisal.⁶

These chemical tests have made possible two attacks on the problem of the drinking driver. The first attack is in court; prosecutions based on the tests have been unusually successful. The second attack is less direct but just as significant; the tests make possible research into the relation of alcohol to accidents. Experimenters are able to find out through their use how much drinking occurs in the accident group of drivers and in the normal driving group; they can find out when this drinking occurs and the age and the sex of the drivers who drink. They can find from these tests just how much more liable a person is to be involved in an accident when he has been drinking than when he has not. Data can be uncovered on the relation between the drinking of drivers and the seriousness of accidents. In other words, by the tests it is possible to isolate an important factor in the accident problem—alcohol. If this important factor can be set apart, one can then more successfully analyze such other causes as speed, lighting, fatigue, inexperience and poor driving habits. These other causes may be more easily, more thoroughly and more accurately analyzed if the complicating factor of alcohol has been isolated. Thus quantitative chemical tests for alcohol are of unquestionable value in the ultimate solution of the accident problem.

With the research value of these tests in mind, the Evanston Police Department, the Northwestern University Traffic Safety Institute, then known as the Northwestern University Traffic Officers Training School, the Evanston Hospital Association, the St. Francis Hospital, the National Safety Council and the

Chicago Motor Club, with Dr. Herman A. Heise as consultant, began on Feb. 1, 1935, a research to determine the amount of drinking involved in accidents which resulted in hospitalization. Urinalyses for alcohol were made for a total of 270 drivers over a period of three years.⁷ Rather good cooperation was obtained from the drivers examined. A representative cross section of all drivers involved in injury accidents was thus obtained.

This experiment produced a figure which represented the percentage of drivers involved in serious accidents who had been drinking. It was a first step in the determination of alcohol as a causal factor in accidents. Not until the next step was taken, however, would this figure assume significance. For example, if it was found that 46 per cent of drivers involved in personal injury accidents had been drinking and then it was found that 46 per cent of all drivers had been drinking, the alcohol consumed would seem to have no bearing on accidents. However, if only 12 per cent of all drivers had been drinking and yet 46 per cent of the drivers involved in accidents had been drinking, it would appear that the drinking drivers were suffering more than their share of mishaps, and drinking would seem to be a causal factor in accidents.

Therefore a study was initiated by the Northwestern University Traffic Safety Institute for the purpose of determining the extent of drinking among drivers; of obtaining, in other words, a "normal group." The "drunkometer," recently developed by Dr. R. N. Harger of the Indiana University School of Medicine for use in court, made such a study possible. This device makes a rapid and accurate analysis for alcohol possible.⁴ In brief, the test is based on the bleaching of an acid solution of potassium permanganate by the alcohol in the alveolar air, which, of course, is part of the normal breath.

The apparatus was set up in a trailer, thus allowing it to be readily moved from location to location throughout the area which approximated the area in which the accidents of the first part of the study occurred. The apparatus, specially built by Dr. Harger, allowed a rapid analysis of the breath samples. Tests of the breath of a total of 1,750 subjects were made in the course of a week. Testing was continuous from midnight Friday, April 22, to 6 a. m. Monday, April 25. Samples were taken from 6 p. m. to midnight Monday, from 6 a. m. to 6 p. m. Tuesday, from midnight Tuesday to 6 a. m. Wednesday, from 6 p. m. to midnight Wednesday, from 6 a. m. to 6 p. m. Thursday, from midnight Thursday to 6 a. m. Friday and from 6 p. m. Friday to 2 a. m. Saturday, April 30 (table 1). This gave a complete sampling over the period of heaviest drinking, the week-end, and alternate daylight and darkness sampling during the week. Over the week-end three crews, each

5. The point representing "conclusive" evidence of alcohol influence was chosen as 0.15 per cent (1.5 parts per thousand) of alcohol in the blood or its equivalent in other fluids or tissues. The *prima facie*, or presumptive, value was chosen as 0.10 per cent of alcohol in the blood or its equivalent.

6. Friedmann, T. E., and Klaas, Rosalind: *The Determination of Ethyl Alcohol*, J. Biol. Chem. 114: 63 (Aug.) 1936.

consisting of four testers, a supervisor and a uniformed police officer, worked on nine hour shifts. These crews were composed of Northwestern University students and police officers (Kemper fellowship students enrolled in the course in traffic police training.)

As about 25 per cent of the accidents in the previous study had occurred in territory where liquor was freely sold and 75 per cent of them had occurred in Evanston

or adjoining suburbs, where liquor is not sold, four of the eight locations chosen were in areas in which it was assumed that drinking drivers would be prevalent. The other four locations were in areas in which it was assumed that drinking drivers would not be very prevalent. The first four locations were on highways passing through Evanston for only a short portion of their length or on streets running into immediately adjoining territory where there were large numbers of taverns. The other four locations, where it was assumed that alcohol would be less prevalent, were well within the interior of Evanston. Actually no difference between the locations was found. This would indicate that because of the ease of movement in motor traffic, at least in limited areas, alcohol is evenly distributed, with little reference to its points of easiest accessibility.

The uniformed police officer stopped all cars in a purely chance order determined by the rate at which the experimenters doing the analyses could work. There was no discrimination as to type or price range of automobile. As soon as the police officer had stopped the car, he immediately retired from the picture so that there would be no hesitancy on the part of the subject through fear of prosecution. No attempt was made to explain the nature of the test to the drivers unless they showed active, intelligent interest in the test and testing procedure. Newspaper publicity was avoided.

Because some difficulty was anticipated in gaining the cooperation of the drivers approached, a technic was very carefully worked out to obtain the samples of breath. After the uniformed officer stopped the car, a tester approached the driver and after a short, set, introductory speech, asked six preliminary questions, such as "Are you bothered by headlight glare?" for the purpose of gaining his cooperation and to allow him to get over the strangeness of the situation. The driver was then presented with the specially constructed wide-mouthed white balloon (the large wooden mouthpiece facilitated inflation) enclosed in a cellophane envelop, so that there would be no possible objection on the grounds of sanitation. The assistants who approached the driver were dressed in physicians' white smocks for the dual purpose of making a favorable impression

on the driver and of making themselves readily visible to other traffic, more especially during the night. Cooperation was readily gained from the drivers with the exception of twenty-four, who refused to be tested.

As soon as the sample of breath was obtained the experimenter wrote the subject's age and sex and the location and time of the test on a tag, which he then attached to the neck of the balloon. The balloon was taken to the trailer laboratory, where one of the testers immediately made a qualitative test on about 1,000 cc. of the breath to determine whether or not alcohol was present. In the event that alcohol was present a quantitative analysis was made on a standard "drunkometer." Breath volume was taken in conjunction with the regular carbon dioxide absorption tube. These tubes were weighed daily at the chemistry laboratory of Northwestern University by graduate students. All the weights were taken on the same balance.

These tests resulted in the establishment of a control group giving an accurate picture of the amount of drinking among drivers in the general population. Analyses were made on the basis of time of day, day of week, sex, age and amount of alcohol present.

THE OCCURRENCE OF DRINKING

The sample of the general population tested showed that about 12 per cent of all the drivers on the road had been drinking and that about 2 per cent of the drivers on the road had been drinking so much that their blood contained 1 part of alcohol to 1,000 parts of blood (or 0.1 per cent), or enough to impair their driving ability. About one driver in every 250 had been drinking to such an extent that his blood contained 1.5 parts of alcohol to 1,000 parts of blood (or 0.15 per cent), enough to place him unquestionably under the influence of alcohol. Table 2 shows this in detail.

The hospital figures (table 3) show that 47 per cent of the drivers involved in personal injury accidents had been drinking, 25 per cent of the drivers so involved had over 1 part of alcohol to 1,000 parts of blood and 14 per cent had over 1.5 parts of alcohol to 1,000 parts of blood.

TABLE 3.—Percentage of Drivers in Personal Injury Accident Group by Blood Alcohol Content

The relationship between the proportions of drivers in each blood alcohol group (1.5 parts per thousand, 1.4 parts per thousand and so on) for the general driving population compared with the accident group is the most significant contribution of this research. It will be discussed in detail later.

The percentage of drinking drivers by two hour periods for the entire week is shown in chart 1 and table 4. As testing was not continuous throughout the week but alternated between daylight and dark, the

resulting gaps in the chart were filled in by substituting the complementary hours of the following day. While this did not result in as accurate a curve as one drawn from a continuous sampling, it is doubtless sufficiently near the real curve for all practical applications. Conclusions that can be drawn from this curve are obvious. It definitely shows, for example, the preponderance of

Suppose, as an example, that 10 per cent of the drivers tested between 10 a. m. and 12 noon at a certain location have been drinking and that, according to previously made counts, 1,000 cars pass the base location during the two hour interval. Thus (assumption 1) of the 1,000 drivers, 100 had been drinking. If then, on this basis during the twelve two hour periods of the day,

Chart 1.—When drivers drink. Percentage of drivers drinking tested in the control group by two hour periods for the week. The unbroken line indicates the percentage drinking and the broken line the percentage drinking on the following day in hours not tested on the day shown (used to give a continuous curve).

drinking over the week-end, a fact of common observation. It should be noted that the peak for Saturday night and Sunday morning goes higher and lasts longer than any other peak. This of course is because Sunday is a holiday.

Because of the relatively few subjects, a similar curve for the personal injury accident group tested is not presented. Fluctuations in the curve would be so great as to render it valueless.

Comparisons have been made, however, on the basis of hour of the day between the personal injury accident group and the general population group. These com-

2,000 drivers passing the base location had been drinking, the 100 drinking from 10 to 12 would represent 5 per cent of the total number drinking in the day. In the case of the accident group no such computation is needed, because the three year experience as taken by the hospitals closely approximates the real distribution.

TABLE 5.—Number of Drinking Drivers by Two Hour Periods of the Day on the Basis of a Total of 100

parisons were made both by the number of drinking drivers per two hour period and by the percentage of drinking drivers tested during each two hour period. Similar comparisons were made on a day of the week basis.

The hour of the day comparison of the accident group and the general population group on the basis of number of drinking drivers is shown in table 5 and chart 2. That this comparison might be made, the curves were drawn on the basis of 100 as the total number of cases in each group. This method of computation is based on two assumptions: (1) that the sample for the location during the two hour period represents the incidence of alcohol in the city for that period and (2) that the volume of traffic at a base location in the city during the period represents the volume of traffic for the city during the period. The base location, incidentally, has been established for years and is constantly used as standard by the city traffic engineer. The volume count at the base location is considered roughly representative of Evanston traffic, so it serves as a constant basis of comparison.

Chart 2.—Number of drinking drivers by hours of the day based on an assumed total of 100. The unbroken line indicates the accident group and the broken line the control group.

In this case it was necessary only to total the cases and find the percentage that each two hour group was of the total.

The charts showing the number of drinkers in the accident group and the normal group are similar in form. While there are certainly divergences in the curves, they can well be accounted for on the basis of small numbers, as the general form of the curves is

nearly the same. The similarity is especially noticeable in the case of the two peaks of both curves. The first is at about 6 in the evening and the other at midnight. The lag of the accident curve might well be the result of the difference between the time of accident occurrence and the time the report was made in the hospital, as often the time of occurrence of the accident was not shown on the card and the time the test was made at the hospital was used.

As both the curve for the accident group and that for the normal group show a peak at 6 p. m. and at midnight, it can correctly be held that such peaks would exist if the entire population was tested. However, caution must be used in assigning causes to these peaks. Possibly (and this is only conjecture) the 6 p. m. peak is the result of the corresponding traffic peak; that is, a large number of persons on the street would tend to imply a large number of persons drinking. The midnight peak might well be the result of an actual increase in drinking in combination with a still relatively large flow of traffic.

These data when presented on the basis of percentage of persons drinking give a somewhat different appearance (chart 3, table 6). Here there is only a single

Chart 3.—Percentage of total drivers drinking by two hour periods. The unbroken line indicates the accident group and the broken line the control group.

TABLE 6.—Percentage of Drinking Drivers by Two Hour Periods of the Day

Two Hour Period	Percentage Drinking, Accident Group	Percentage Drinking, Control Group
12-2 a. m.	64.0	40.8
2-4	80.0	50.0
4-6	100.0	35.0
6-8	66.6	10.2
8-10	20.8	6.8
10-12	28.2	12.8
12-2 p. m.	13.2	8.6
2-4	20.8	6.5
4-6	20.8	11.7
6-8	58.6	9.9
8-10	45.4	10.0
10-12	43.7	16.3

peak, in contrast to the double peak shown in the case of the number of drinking drivers. Also the peak occurs much later. The curve for the general population group is quite regular, increasing till early morning, dropping sharply, running on a level from about 6 in the morning till 8 in the evening and then increasing till about 3 a. m. A peak showing 50 per cent of the drivers on the road as having been drinking is then

reached. The curve for the percentage of drivers in personal injury accidents is similar though somewhat more irregular. This irregularity can be discounted to a large extent because of the smallness of the sample. A peak is reached in the period from 4 to 6 a. m. of 100 per cent drinking. This, however, is in all probability a result of the smallness of the sample, though doubtless the true peak would be quite high. A lag is also to be noted that is similar to the lag of the accident

Chart 4.—Number of drinking drivers by day of the week on the basis of an assumed total of 100. The unbroken line indicates the accident group and the broken line the control group.

TABLE 7.—Number of Drinking Drivers by Days of the Week on the Basis of a Total of 100

Day of Week	Accident Group	Control Group
Sunday.....	31.2	22.01
Monday.....	9.6	9.0
Tuesday.....	11.2	10.8
Wednesday.....	8.0	12.6
Thursday.....	10.4	13.5
Friday.....	18.4	12.6
Saturday.....	11.2	10.2

group in the charts just discussed, where the number of drinking drivers was presented, and it can probably be accounted for in the same way.

Chart 4 and table 7 present the number of drinking drivers in each group by days of the week. For purposes of comparison, as in the case of the hour of the day presentation, these data were reduced to a percentage basis to obtain comparable curves. One point must be noted in the presentation of this curve; because the sample taken (table 1) included alternate periods of daylight and dark on alternate days during the week and if used uncorrected would result in an inaccurate representation, a correction was made. This correction consisted in combining the score for each day with that of the following day in the case of Monday and the previous day and the following day in the case of Tuesday, Wednesday and Thursday. This is better illustrated in table 8.

Again there is a striking similarity between the accident group and the control group. The control group again presents a very regular curve, while the curve for the accident group, because of the small numbers, is somewhat more irregular, although running quite close to that of the control group. The peak for both groups occurs over the week-end, Saturday and Sunday. The peak is actually reached early Sunday morning, as shown in the chart for the week by hours. Thus the largest number of persons drinking is found early Sunday, with the number dropping off sharply and then gradually increasing till the next week-end.

The points discussed in connection with number of persons drinking would apply equally well in a discus-

sion of the percentage of persons drinking (chart 5, table 9). Unlike the peak for hour of the day, the traffic peak for days of the week and the peak for percentage of drinking are the same. The curve for the percentage of drinking drivers in personal injury accidents is irregular in comparison with the curve for the normal group, and the week-end increase is followed by a sharp drop and then a gradual build-up to the week-end. It should be noted that there are over twice as many drinking drivers during the week-ends as on week days.

TABLE 8.—Correction for Curve Shown in Chart 7

Sunday	A complete day, no correction	
Monday (dark)	Average of Mon. and Tues. Used for Monday score	
Tuesday (light)	Average of Tues. and Wed.	Average of Mon., Tues. and Wed. Used for Tuesday score
Wednesday (dark)	Average of Wed. and Thurs.	Average of Tues., Wed. and Thurs. Used for Wednesday score
Thursday (light)	Average of Thurs. and Fri.	Average of Wed., Thurs. and Fri. Used for Thursday score
Friday (dark)	A complete day, no correction	
Saturday	A complete day, no correction	

Unfortunately no data were secured as to the age of the drivers in the personal injury accident group. However, the results of an age tabulation in the control

Chart 5.—Percentage of drivers drinking by day of the week. The unbroken line indicates the accident group and the broken line the control group.

TABLE 9.—Percentage of Drinking Drivers by Days of the Week

Day of Week	Accident Group	Control Group
Sunday.....	67.2	21.5
Monday.....	46.2	10.0
Tuesday.....	45.1	11.5
Wednesday.....	31.3	13.4
Thursday.....	41.9	14.0
Friday.....	51.1	14.2
Saturday.....	29.2	18.6

study are of interest (chart 6, table 10). A definite peak showing over 28 per cent of drinking drivers is found at the age level from 25 to 30 and is followed by a gradual decline. The extreme lower and the extreme upper age limits were not determined, but the lower limit was probably about 16 or 17 and several persons in the 70's were tested.

Little comment is needed on the significance of this curve. It follows quite closely the expected. It is an accurate indication of the relation between age and driving after drinking.

Since there are many more men drivers than women and women do most of their driving during the day, a much smaller percentage seemed to have been drinking.

Chart 6.—Percentage of drinking by age. The unbroken line is for men, the line marked with crosses for women and the broken line for all cases.

TABLE 10.—Percentage of Total Drinking by Age

Age	Men	Women	Total
17-20.....	5.7	0	4.8
20-25.....	15.5	10.3	14.9
25-30.....	27.7	12.0	26.2
30-35.....	18.4	21.2	18.7
35-40.....	19.5	6.7	18.1
40-45.....	19.7	0	16.6
45-50.....	15.7	0	14.6
50-55.....	15.5	0	14.3
55-60.....	10.0	0	8.7
60 and over.....	6.9	0	5.9

However, when the figures are presented on the basis of percentage drinking by hour of the day (chart 7, table 11) there is little difference between the curve for men and that for women. The peak reached by women at 4 and 5 a. m. is probably spurious and due to the small number of cases, as very few women proportionately were driving at that time. Additional data are needed here to smooth out these curves. No tabulation on the basis of sex was made in the accident group because of the smallness of numbers.

RELATION OF ALCOHOL TO ACCIDENTS

There are thirty-three times as many drivers whose blood contains 1.5 parts per thousand of alcohol in a group of drivers involved in personal injury accidents as in the general driving population. There are ten times as many whose blood contains 1.3 parts per thousand as there are in the general population. Presented graphically, these are two points on a regularly descending curve that approaches a ratio of 1 to 1 at some point near 0.5 part per thousand. The correlation between alcohol in the blood and increased accident expectancy was worked out on the basis of the data of this study at 0.76 (plus or minus 0.07).

The point in the alcohol content of the blood at which this 1 to 1 ratio is reached, that is, the point at which the same percentage of drivers appears in the personal injury accident group as in the general population, is of considerable significance. There has been much discussion of the relation between alcohol in the blood and intoxication, based both on observation and on the use of objective tests, in an attempt to set a point at which the drinking driver should be removed as potentially dangerous. The curve mentioned (chart 8, table 12) goes far toward showing where this point occurs, for, as soon as more drinking drivers appear in the personal injury accident group than in the general population,

the ratio goes over 1 to 1. Alcohol can be considered as causing this increase in accidents over the expected. From these data it would appear that this point is about 0.5 to 0.6 part of alcohol to 1,000 parts of blood. Additional cases are needed here to obtain a smoother, more reliable, curve. It is not suggested that

Chart 7.—Percentage of drinking by hours of the day on the basis of sex. The unbroken line is for men and the broken line for women.

TABLE 11.—Percentage of Drinking by Two Hour Periods on the Basis of Sex

Two Hour Periods	Entire Group	Women Only
12-2 a. m.	40.8	44.4
2-4	50.0	40.0
4-6	35.0	100.0
6-8	10.2	16.7
8-10	6.8	4.0
10-12	12.8	2.0
12-2 p. m.	8.6	0

4-6	11.7	0
6-8	9.9	5.3
8-10	10.0	18.2
10-12	16.3	4.3

a point for the blood alcohol content just over the 1 to 1 ratio be used for other than prima facie evidence of intoxication, but the location of this point should go far toward determining the lower limits of blood alcohol at which persons are considered under the influence of alcohol.

Thus a concomitant variability is demonstrated. It has been shown further that there are several times as many drinking drivers in accidents as in the general driving population. But does a causal relationship exist? In other words, is this increase in alcohol actually the cause of the increased accidents? Is there possibly a factor or factors causing both the increase in alcoholic content of the blood and the increase in chances of accident? Would there be any basis for advancing some other cause for this relationship?

Among other possible causes, might not a common one be darkness? Could this relationship exist because people normally drink at night, when darkness with its effect on visibility, causes personal injury accidents to increase? People drink at night because they have free time then; accidents happen at night, when visibility is poor. Then is this relationship between accidents and alcohol just chance? Is darkness really the cause? Table 13 and chart 9 prove that this is not the case. Personal injury accidents when related to the amount of traffic on the road, or exposure, have their peak after midnight. (Divide the traffic count by two hour periods by the personal injury accidents by two hour periods.) If darkness was the cause of this increase, it would be

logical to expect the curve to be approximately the same during all hours of darkness. Instead, on the average it is 2.35 times as high in the hours of darkness after midnight as it is in the hours before. Alcohol, it must be remembered, has its peak after midnight, just as do personal injury accidents (table 6 and chart 3).

However, it might be argued that speeds increase. True, but why do they increase? There are two possible major causes. The first is the decrease in congestion and the second the increase in alcohol. Any increase in speed as a result of a decrease in congestion would tend to be offset as a causative factor by the decrease in congestion. While speed doubtless plays an important part in causing accidents, it might well be treated as a symptom of an underlying cause. Certainly alcohol, with its removal of inhibition, might well be a cause of increased speeds and thus of accidents. It must further be remembered that, unlike decreasing congestion, alcohol offers nothing to compensate for the increase in speeds which it causes. Rather, by increasing reaction time and decreasing perceptual ability⁷ it makes the speed still more dangerous.

Fatigue⁸ might be a cause of accidents occurring at such times and in such amounts as to displace alcohol

Chart 8.—Number of times drivers in the accident group are of control in the control group for each amount of blood alcohol. The broken line shows the curve smoothed.

TABLE 12.—Number of Times Accident Group is of Control for Each Amount of Alcohol

Blood Alcohol Content	Times (Accident Group Over Control)	Accident Group Is of Control (Smoothed Curve [Average at 2 Parts])
1.5 and above	33.12	21.08
1.4	5.34	
1.3	10.80	13.03
1.2	14.54	
1.1	7.30	6.50

0.9	1.28	1.75
0.8	2.08	
0.7	4.23	2.39
0.6	0.41	
0.5	0.48	0.45
0.4	0.52	
0.3 or less	2.93	2.91

as the assumed cause of accidents. Certainly, like drinking, fatigue occurs most commonly at night. Like drinking too it results in diminished ability to drive. However, an examination of the facts will show that

7. Miles, W. R.: Psychological Effects of Alcohol on Man, in Emerson, Haven: Alcohol: Its Effects on Man, New York, Macmillan Company, 1935, chapter 10.

8. Fatigue for the purpose of this discussion is taken to mean the effects of prolonged activity whether they have only an actual physical basis, such as an actual physical disability, or only a mental basis, such as the effect of monotony, or a combination of these two.

it would be impossible for fatigue to account more than superficially for the increase in accidents associated with alcohol.

It is difficult to study the problem of fatigue. No methods that will reliably and validly measure fatigue are available. Actual physical losses in ability are difficult to disassociate from the effects of monotony, as the results of the two factors may be the same. Numerous attempts have been made to measure, subjectively at least, the physical aspects of fatigue, but all too often the results have failed to be conclusive. One measure of fatigue that has found general acceptance is accident records. Long experience in industry has shown that accidents increase in proportion to the time spent at work, with slight decreases as monotony is relieved as the end of the working period approaches. It is probably safe to assume that the curve for automobile accidents caused by fatigue⁹ would be similar to that obtained for accidents caused by the driver's falling asleep. Difficulties in assigning causes of accidents may have resulted in some inaccuracies, but the general shape of this curve is reliable. It shows that the largest number of accidents caused by the driver's falling asleep occurs at about 4 o'clock in the morning. Comparison of this curve with the curve showing the number of drinking drivers or that showing the number of personal injury accidents involving alcohol shows little relation. While the fatigue curve has its peak in the early morning hours, the curve for drinking drivers and the curve for accidents have their peaks in the early and late evening hours.

There are several further bits of evidence tending to prove alcohol rather than fatigue the prime causative factor. First, in the area of this experiment fatigue would be at a minimum. The largest part of the area was unquestionably urban, with a heavy flow of traffic. The average driver would be driving only a comparatively short distance. Because of this fact and the nature of the route, monotony would not be the important factor in causing fatigue that it might be on a highway, where there would be no relief from driving at a relatively constant speed on long stretches of road. Another reason to minimize fatigue is that any data gathered on fatigue as a cause of accidents tend to place it as a causative factor in not more than 2 or at the most 3 per cent of the accidents. The most reliable study so far reported, done in Massachusetts by the Registry of Motor Vehicles and based on actual investigations rather than drivers' reports, shows that 1.98 per cent of the total accidents were caused by sleep or fatigue. Contrast that with this study, which shows that 47 per cent of drivers had been drinking and that 14 per cent had drunk so much that they were unquestionably under the influence of alcohol. Several other points should be noted in passing. For instance, and no experimental evidence exists to back this statement, quite possibly the fatigued driver is more inclined to compensate for his disability than is the drinking driver. Probably the fatigued driver will slow down and in general drive more carefully than the drinking driver. Of prime importance is the ability to recover much more readily from fatigue than from alcohol. Stopping the car, getting out and walking, drinking coffee and other measures will at least temporarily dispel fatigue. This, unfortunately, is not true of alcohol.

With the data at hand it is impossible to make an accurate, complete statement of the relation of fatigue

and alcohol as causes of accidents. The previous discussion has of necessity been based more on conjecture than on facts. One point, however, must always be remembered in any discussion of this problem; the effects of fatigue are always heightened by alcohol. Reaction times slowed up by fatigue are even slower when alcohol is present. Vision blurred by need for rest is even more blurred with the addition of alcohol. Fatigue can and does cause a large number of accidents, but all available evidence tends to minimize it as a cause when compared with alcohol.

Another reason for this concomitant variability of personal injury accidents with drinking should be

TABLE 13.—Personal Injury Accidents (Drinking and Non-drinking Drivers) Related to Traffic by Hour of the Day

8-10	3.8
10-12	2.1

Chart 9.—Personal injury accidents related to traffic, expressed as percentage of total traffic and then based on an assumed total of 100.

considered. Possibly the person who drinks is the one who ordinarily drives recklessly and is prone to accidents. Perhaps a certain mental makeup is expressed in drinking and also in proneness to accidents. No positive answer can be given to this question. The possibility is minimized, however, when one considers that the person prone to accidents is even more prone to them after drinking, for alcohol unquestionably increases reaction time and affects vision, ability to coordinate, judgment and the other abilities so necessary in the operation of a motor car. Until experimental evidence is presented to prove otherwise, it seems logical to accept the fact that not speed, not darkness, not inherent proneness to accidents in drivers who drink, but rather alcohol, with its demonstrable effects, is the major cause of the high proportion of personal injury accidents in the hours after midnight. The part

9. Baker, J. S.: Too Long at the Wheel (pamphlet), National Safety Council, 1935.

of these other factors, though, should not be forgotten. Additional work is needed to determine their relation to the accident problem. They unquestionably exist and in themselves do cause accidents. It must be further remembered, however, that alcohol will definitely heighten the effect of any or all of these factors. Thus poor visibility because of darkness is even poorer when the driver has been drinking; increased speeds become more hazardous after alcohol has increased reaction time; drivers prone to accidents become more so after the depressive effects of alcohol release their inhibitions; the effects of fatigue are increased by drinking.

If alcohol is a general, basic, underlying cause of personal injury accidents, two things would be expected:

1. As alcohol varies, personal injury accidents should vary. That is, an increase or decrease in the percentage of drinking drivers should be accompanied by an increase or decrease in the percentage of drivers involved in personal injury accidents.

2. As alcohol varies, personal injury accidents involving alcohol should vary. That is, an increase or decrease in the percentage of drinking drivers should be accompanied by an increase or decrease in the percentage of personal injury accidents in which one or more of the drivers had been drinking.

The first statement is proved by a correlation between the percentage of drinking drivers by two hour periods with the percentage of drivers in personal injury acci-

Chart 10.—Relation between the percentage of drinking drivers in the general population by hours and the percentage of drivers in the personal injury accident group by hours, based on an assumed total of 100. The broken line is for the accident group and the unbroken line for drinking drivers (control group).

TABLE 14.—Relation Between Percentage of Drinking Drivers by Hours and Percentage of Drivers by Hours in Personal Injury Accidents Based on an Assumed Total of 100

Two Hour Periods	Personal Injury Accidents	Drinking Drivers
12-2 a. m.	4.3	9.3
2-4	6.3	11.5
4-6	9.5	8.0
6-8	2.7	2.4
8-10	3.6	1.5
10-12	3.9	3.0
12-2 p. m.	4.1	2.0
2-4	2.7	1.5
4-6	3.4	2.7
6-8	3.3	2.3
8-10	3.7	2.3
10-12	2.1	3.7

dents, corrected for traffic, of 0.68 plus or minus 0.08. Chart 10 and table 14 further illustrate this point. In other words, it is demonstrated that there is a rather close correlation between drinking and personal injury accidents.

The second statement is proved by a correlation between the percentage of drinking drivers by two hour periods and the percentage of drinking drivers involved

in accidents of 0.73 plus or minus 0.07. It is further borne out by chart 4, which illustrates the close time relation of these two groups.

One more significant fact pointing toward alcohol as a causative factor must be noted. As personal injury accidents exceed traffic, drinking increases, and as the curve representative of this relationship drops, so does

TABLE 15.—Relation of Personal Injury Accidents to Traffic

(Number of times percentage of total by two hour periods personal injury group is of traffic or vice versa)

Hour of Day	Times Greater Personal Injury Accidents Are Than Traffic	Times Greater Traffic Is Than Personal Injury Accidents
12-2 a. m.	1.23
2-4	1.86
4-6	2.73
6-8	1.32
8-10	1.04
10-12	1.14
12-2 p. m.	1.16
2-4	1.28
4-6	1.62
6-8	1.06
8-10	1.10
10-12	1.68

the curve for drinking drivers (table 15). In other words, as personal injury accidents increase over the expected, drinking drivers increase similarly. It seems entirely logical to place the responsibility for this increase in accidents with alcohol. A definite concomitant variability has certainly been demonstrated, and evidence has been given to show that a causal relationship must exist.

Thus it appears that a close causal relationship exists between alcohol and accidents.

CONCLUSIONS

1. The highest percentage of drinking drivers occurs in the early morning hours and over the week-end.
2. The largest number of drinking drivers occurs in the early evening and over the week-end.
3. The peak age for drinking drivers is from 25 to 30.

4. Women drink and drive as much as men when the number of women driving at various hours of the day is considered.

5. The percentage of drinking drivers in the general population varies as does the percentage of drinking drivers in the personal injury accident group but falls considerably lower at all times.

6. The percentage or number of drivers involved in personal injury accidents varies as does the percentage or number of drinking drivers.

7. As the blood alcohol content increases, the number of drivers appearing in the personal injury accident group increases out of all proportion over that in the general driving population.

8. As alcohol increases, accidents increase and at a rate somewhat proportionate to the increase in alcohol.

9. Equal percentages of drinking drivers are found in the accident group and in the general population group at a point near 0.5 part of alcohol per thousand parts of blood, indicating that alcohol in that amount is not necessarily a significant cause of accidents.

10. It has not yet been objectively and conclusively proved just how important a causative factor alcohol is, and, because of the complexity of the whole accident problem, it may never be proved. The data gathered in this study, however, point in one direction only. They confirm a self-evident fact, that alcohol is a major cause of automobile accidents.

SUMMARY

A study was made of the drinking of drivers involved in personal injury accidents and of the drinking of drivers in the general population. The second study served as a control of the first, allowing conclusions to be drawn as to the part alcohol plays in accidents.

A total of 270 persons were tested in the first study. Drivers involved in personal injury accidents who accompanied the persons injured to a hospital or drivers who themselves were injured were tested by urinalysis for alcohol.

A total of 1,750 persons were tested in the second study. Drivers were chosen at random from an area comparable to that of the first study. A complete testing laboratory, with the Harger "drunkometer," was set up in a trailer, allowing breath tests for alcohol to be made immediately.

Comparisons were drawn between the accident and control groups on the basis of hour of the day, day of the week and blood alcohol content. The control group was presented on the basis of age as related to drinking and sex as related to drinking. The time and the amount of drinking were related to the time and the number of personal injury accidents.

ANOREXIA NERVOSA

A METABOLIC DISORDER OF PSYCHOLOGIC ORIGIN

R. F. FARQUHARSON, M.B.

AND

H. H. HYLAND, M.D.

TORONTO

In 1873, under the title of "anorexia nervosa," Sir William Gull¹ described a syndrome characterized by extreme emaciation and amenorrhea in the absence of any demonstrable structural disease. The illustration is a reproduction of the pictures of one of his early patients before and after treatment. About the same time Lasègue² described the condition as "hysterical anorexia." Numerous articles on the subject since then have added little to the clear, concise accounts of these authors.

The disorder occurs chiefly in adolescent girls, less commonly in men. Following some prolonged emotional conflict, either avowed or concealed, the appetite fails and the intake of food becomes grossly insufficient, leading to loss of weight. Commonly there are mild symptoms, such as uneasiness after food, epigastric distress or constipation, which provide a further excuse for the anorexia. Emaciation increases and the patient's health becomes an object of great concern to her family. Yet she remains quick, alert, active and restless and denies ill health until emaciated to a degree not seen in patients with organic disease still able to get about. "These wilful patients are often allowed to drift their own way into a state of extreme exhaustion, when it might have been prevented by placing them under different moral conditions" (Gull). When emaciation

is at its greatest, weakness increases and edema of the lower extremities may supervene. Occasionally death results from starvation. Amenorrhea may appear early or only after considerable loss of weight has occurred. When the syndrome is well developed the temperature is often subnormal, the pulse rate and the blood pressure low.

Ryle³ remarks on the tendency of "physicians subject to the lure of endocrinology" to look for the cause of this syndrome in a primary deficiency or disharmony of the internal secretions. The ovaries, thyroid, adrenals and pituitary have all been blamed. In recent years attention has been directed more and more to the hypophysis, and the finding of low basal metabolic rates and altered sugar tolerance, in addition to emaciation and amenorrhea, would appear to support this idea. Recently Sheldon⁴ has suggested that anorexia nervosa, which he recognizes clearly as a definite syndrome, may be "a 'functional' Simmonds' disease—a pituitary 'black-out' of psychological origin." This conception has won the approval of others.⁵

On the other hand, in the literature on Simmonds' disease one finds reports of many cases that appear to present the typical picture of anorexia nervosa. Some of these patients have responded well to the administration of various pituitary extracts and their recovery has been taken as evidence of the correctness of the diagnosis of Simmonds' pituitary cachexia. The two syndromes have a superficial similarity but, in our opinion, they are fundamentally different.

It is our purpose in this paper to report eight cases of anorexia nervosa and to point out in discussion the nature of the disorder and its various manifestations. Reasons will be presented to support the belief that this metabolic disorder is based primarily on psychologic disturbance and that its various manifestations should not be attributed to dysfunction of any endocrine gland.

REPORT OF CASES

The following case histories are reported in brief. All the patients were carefully examined and special investigations were carried out as indicated. Negative observations, however, are mentioned only if of particular significance.

CASE 1.—E. L., a Jewish girl, aged 15, was admitted to the hospital Feb. 11, 1932. She had come to the outpatient clinic because her mother was concerned about the patient's loss of weight. Five months previously she weighed 75 pounds (34 Kg.) but had gradually lost 16 pounds (7 Kg.) during that time. Menstruation had commenced in 1930. The periods were fairly regular, occurring every twenty-eight days until September 1931, since which date she had not menstruated. She stated that she did not have any gastrointestinal symptoms but said that she had been eating very small meals because of abdominal discomfort that followed a large intake of food.

The patient was emaciated. She did not appear acutely ill but was apprehensive about being in the hospital. The secondary sex characteristics and distribution of hair were essentially normal. There was no anemia. The blood pressure was 82 systolic, 50 diastolic, the basal metabolic rate —37 per cent, the pulse rate from 60 to 95 per minute, the temperature from 96 to 99 F. The fasting blood sugar determined on six occasions varied between 69 and 77 mg. per hundred cubic centimeters. The first sugar tolerance curve (100 Gm. of dextrose) showed a slow and prolonged rise; after eight days, during which time she began to eat voraciously, the test was repeated with only 50 Gm. of dextrose and the curve was flat (table 1).

From the Department of Medicine, University of Toronto, and the Medical Service, Toronto General Hospital.

Prof. Duncan Graham gave the authors permission to report cases 1, 3, 4, 5 and 6, and Prof. C. B. Farrar and Dr. Trevor Owen gave permission to report case 7.

1. Gull, W. W.: *Anorexia Nervosa (Apepsia Hysterica; Anorexia Hysterica)*. Clin. Soc. Tr. 7: 22, 1874. In 1868 Gull (Address in Medicine, Lancet 2: 171, 1868) had used the term "hysterical anorexia" to describe the same condition.

2. Lasègue E. C.: *On Hysterical Anorexia*, M. Times 2: 265, 1873 (translated from Arch. gen. de med., 1873)

3. Ryle, J. A.: *Anorexia Nervosa*, Lancet 2: 893 (Oct. 17) 1936.

4. Sheldon, J. H.: *Anorexia Nervosa with Especial Reference to Physical Constitution*, Lancet 1: 369 (Feb. 13) 1937.

5. Langden-Brown, Walter: Lancet 1: 473 (Feb. 20) 1937. Dunn, C. W., *ibid.* 1: 723 (March 20) 1937.

At the time of admission her perceptions were a little slow and her memory defective. Emotionally she was fairly stable. On enquiry she stated that she had been worried and unhappy at home for the past six months and that this had contributed to her lessened intake of food. The only causes for worry that she would admit were the cessation of menstruation and the fact that her mother was "always fussing about her."

Under observation in the hospital, she showed considerable variability in mood. Most of the time she seemed content and cheerful, but there were days when she was depressed and uncommunicative. A hypochondriacal trend developed and she talked at great length about her digestive system. She said that she could not taste food properly and demanded an x-ray examination of her intestine because there seemed to be something wrong with the passage of food through it. She complained that she did not have the proper feeling when her bowels moved and asked that this be investigated. Under reassurance her appetite increased greatly and she commenced to eat ravenously and complained that no matter how much she ate she was never satisfied. On discharge from the hospital, February 23, her weight was 64½ pounds (29 Kg.) and basal metabolic rate —28 per cent.

The diagnosis lay between anorexia nervosa and acquired anterior pituitary deficiency. Despite the normal appearance

Patient with anorexia nervosa, before and after treatment (Sir W. W. Gull, 1873).

of secondary sex characteristics and the normal distribution of body hair, the latter diagnosis was favored.

After discharge she was given injections of antuitrin 1 cc. intramuscularly twice a week, from March to July 1932. Her appetite continued to increase.

On readmission to the hospital for ten days in April she was found to be eating 3,400 calories each day. Her weight was 73 pounds (33 Kg.), the basal metabolic rate —16 per cent, the blood pressure 102 systolic, 52 diastolic. Her general appearance was much improved but she was still introspective and hypochondriacal.

Examination October 31, three months after antuitrin therapy was discontinued, showed a marked improvement in her mental attitude. The excessive desire for food had subsided and she was eating ordinary amounts. She was bright and agreeable and was taking part in games at school. She no longer displayed obsessions about her gastrointestinal tract. This improvement was maintained. Menstruation returned in November 1933 and was regular thereafter. Her weight in January 1934 was 86 pounds (39 Kg.), height 4 feet 8 inches (142 cm.), basal metabolic rate —5 per cent, blood pressure 112 systolic, 76 diastolic. Mentally and emotionally she appeared normal. In view of the continued improvement after cessation of endocrine therapy it was felt that a diagnosis of anterior pituitary insufficiency was untenable and that the diagnosis of anorexia nervosa was established.

The patient was seen again Feb. 19, 1938. She had been working in a factory for the past four years and had not missed

any time owing to ill health. There had been no gastrointestinal symptoms whatever. Menstruation had occurred normally every four weeks during this time. Her height was 4 feet 8¼ inches (142 cm.), weight 99½ pounds (45 Kg.), blood pressure 122 systolic, 84 diastolic. The patient stated that she realized that her former illness was the result of a desire on her part to have things her own way in the home. Her two sisters and a brother, all older than herself, were living at home and would order her about. When she was sick her mother became very anxious and would take her part, aiding her in getting her own way. The two sisters and brother are now married and living elsewhere. Her life at home has been quite congenial since they departed.

CASE 2.—D. K., a girl aged 18, first examined May 8, 1933, was in good health—weight about 108 pounds (49 Kg.)—until the autumn of 1932, when she was sent to boarding school. Her menstrual periods ceased at that time. Because of a coincident gradual increase in weight to 120 pounds (54 Kg.) she began to restrict her diet, avoiding carbohydrates and fats. Progressive loss of weight resulted. Her appetite remained good but she began to complain of epigastric fullness whenever she ate more than a small quantity of food. She tired easily and worried greatly about constipation, which she believed was responsible for her symptoms. In January 1933 she menstruated once but had not menstruated subsequently. Since February, worry about her condition had led to difficulty in sleeping.

The patient was very thin but otherwise well developed. height 5 feet 4 inches (163 cm.), weight 91 pounds (41 Kg.), temperature 98.6 F., pulse rate 60 per minute, blood pressure 98 systolic, 70 diastolic. There was no anemia. Her hands were cold and reddish blue. The colon was palpable and tender. Enquiry showed that the patient had always been ambitious, sensitive and conscientious. She had done well at school and was working very hard because she dreaded mediocre standing. Her mother suffered with paralysis agitans and the patient tended to be depressed when at home.

A diagnosis of anorexia nervosa was made.

By June her weight had fallen to 88 pounds (40 Kg.). She took high standing in matriculation examinations and returned to her home in the country, refusing to be admitted to the hospital for more complete investigation and treatment. During the subsequent year at home her weight gradually went down to 70 pounds (32 Kg.). On investigation at another medical center in the summer of 1934 the basal metabolic rate was found to be —25 per cent; thyroid extract 1½ grain (0.1 Gm.) daily was prescribed. In the autumn of 1934 the patient entered the university and following this showed gradual improvement. By Christmas her weight had increased to 93 pounds (42 Kg.). When seen Jan. 31, 1935, her weight was 100 pounds (45 Kg.), she was eating well and she had menstruated a few weeks before. She is now married.

CASE 3.—R. V., a man aged 21, admitted to the hospital Dec. 3, 1933, was in his usual state of good health until June 1931, when he commenced to lose his appetite. Desire for food gradually decreased and was associated with progressive loss of weight and a feeling of fatigue. There were no other complaints apart from an occasional sensation of nausea. During the interval of two and a half years from the onset, his weight decreased from 153 pounds (69 Kg.) to 108 pounds (49 Kg.). The patient was not inclined to discuss his condition in detail and did not appear greatly concerned about it. He explained that he had often tried to eat larger quantities of food but had found that whenever he took more than a small amount he was troubled with epigastric fullness and nausea.

The patient was well developed but extremely emaciated and was in no apparent discomfort. His height was 5 feet 9 inches (175 cm.) and weight 101 pounds (46 Kg.). Hair distribution and secondary sex characteristics were normal for his age. The blood pressure was 95 systolic, 58 diastolic, the basal metabolic rate —25 per cent. His sugar tolerance curve was low and flat (table 1). There was no anemia. The pulse rate was from 64 to 85 per minute, the temperature from 97 to 98.6 F.

He had a good mentality; memory, perception and attention were not impaired. He was not depressed and appeared

anxious to regain his health. Enquiry showed that he had always tended to be seclusive but, although he did not make friends easily, he never had difficulty in getting along with people. His parents and an older brother lived on a small farm. Two years previously the patient had been sent to a neighboring city to find work but he had not been successful. He made few friends and became dissatisfied with the idle life he was leading. He wished to return to the farm but his parents would not agree. The patient became worried about their attitude and jealous of his brother. It was at this time

The patient was assured that there was no organic disease and the nature of his symptoms was explained to him. A duodenal tube was passed and left in situ for thirteen weeks. Eight concentrated feedings of 260 calories each were administered at intervals of two hours daily. After his fear had been allayed that the stomach might be abnormally stretched, he showed steady improvement. In about two weeks' time he was encouraged to take nourishment by mouth as well as by tube. With the increase in food intake an irregular low grade fever developed and persisted for about two months.

		1938 May	24	59	112/60		

that he commenced to suffer from indigestion after meals, which consisted mainly of a feeling of fullness, and to get relief he gradually cut down on his food intake. He stated that prior to his illness he ate very large meals and frequently ate between meals. To this excess he attributed the gastric disturbances which resulted in his present illness. He stated that there had been no loss of appetite but that he had a constant fear of the discomfort which invariably followed eating even a moderate quantity of food.

He was referred to the hospital as having Simmonds' disease. Because of the lack of evidence of gross endocrine dysfunction and the presence of an obvious psychologic disorder, the extreme emaciation was believed to be due to anorexia nervosa.

Eight weeks after admission, his weight was 113½ pounds (51.5 Kg.), the basal metabolic rate -29 per cent. The patient stated that he felt much stronger and eagerly anticipated his meals. He was more talkative than on admission and was frequently seen chatting with the other patients in the ward. The dextrose tolerance curve had become more normal (table 1). When the duodenal tube was withdrawn the patient was eating a diet of 3,000 calories daily. His weight was 128 pounds (58 Kg.) and the basal metabolic rate was -6 per cent.

On discharge from the hospital, March 30, 1934, his weight was 131 pounds (59 Kg.), the basal metabolic rate -10 per cent. Mentally much improved, he regarded the future with optimism and was completely reassured regarding his digestive

disturbances. Information received July 25, 1934, indicated that he was well, weighed 140 pounds (63.5 Kg.) and was working happily on the farm.

CASE 4.—D. G., a boy aged 13, admitted to the hospital Jan. 24, 1934, was brought to the hospital by his parents because of loss of weight and a peculiar mental attitude toward food. He had developed normally until the spring of 1933, at which time he was a little heavier than most of his play fellows. The other boys called him "Tubby" and "Fat," which annoyed him greatly and resulted in several fist fights. He informed his parents that he was dieting to reduce weight. From that time on he took an abnormal interest in food. He talked about it constantly, with particular reference to the fat-producing ingredients of various dishes, and secretly took a "patent medicine" to aid in reducing. He would slip food into a paper bag between his knees during meals and afterward burn it in the furnace. It was noted that he would wipe the butter off his bread and put it on the under surface of the seat of his chair. Over the period of a year his weight decreased from 115 pounds (52 Kg.) to 79 pounds (36 Kg.). His parents stated that during this time he had become suspicious of people and would sneak around the house listening to conversations on the assumption that people were talking about him. He had become greatly interested in music, which previously had not interested him at all. His aunt stated that the boy would go into the woods alone and pray to become thin, and that he had expressed an idea that his bedroom was holy.

TABLE 2.—Effect of Administration of Desiccated Thyroid in Case 5

Date	Basal Metabolic Rate, %	Thyroid Medication
Sept. 6, 1934.....	-37	Desiccated thyroid, 1 gr. daily, Sept. 1933 to Sept. 24, 1934
Sept. 28, 1934.....	-25	Receiving no thyroid
Nov. 5, 1934.....	-23	Receiving no thyroid
Jan. 5, 1935.....	-30	Desiccated thyroid, 1 gr. daily, Nov. 11, 1934 to March 1935
Jan. 26, 1935.....	-34	
May 6, 1935.....	-17	Receiving no thyroid
Mar. 17, 1938.....	-17	Receiving no thyroid

Prior to his illness he had been healthy and strong, living happily with his parents and one older sister. He had done moderately well at school but preferred to stay at home and occupy himself with mechanical toys rather than play games with the other boys. His outside doctor had found his basal metabolic rate to be -39 per cent and for sixteen days prior to admission the patient had been receiving 1 grain (0.065 Gm.) of desiccated thyroid daily but had shown no improvement.

The patient was extremely emaciated; his height was 5 feet 4 inches (163 cm.), his weight 74½ pounds (34 Kg.). The secondary sex characteristics were normally developed for the age of the patient. There was no anemia. The basal metabolic rate was -45 per cent, the blood pressure 108 systolic, 70 diastolic, the pulse rate from 60 to 90 per minute, the temperature from 97 to 100 F. The sugar tolerance curve tended to be rather low (table 1).

It was ascertained that the father was an emotionally stable person with a good deal of understanding but that the mother was a highly strung, overly conscientious person who failed to take the boy's point of view into consideration and was constantly correcting him and endeavoring to make him conform to her standards. The patient had always been considered a nervous child, subject to impulses and full of short-lived enthusiasm for various interests. About two years previously his family moved to their present home in a different part of the city and, as the patient found difficulty in making friends in his new environment, he spent much time by himself. He stated that at first he intended to stop dieting when his weight fell to 100 pounds (45 Kg.) but that he found it impossible to do so. He admitted being influenced by the thought that if he lost much weight and became very thin he would attract a great deal of attention. As a result, he made a study of food values and stated that he became angry and suspicious of people who

tried to persuade him to eat the regular meals. In conversation he appeared to be bright and alert; memory, perception and attention showed no defects. He stated that the family, particularly his mother and sister, were against him and that they were ignoring him and leaving him at home rather than taking him to shows and other places of amusement. He had arrived at the conclusion that there was not much in life worth living for.

During his stay in the hospital the nature of the condition was explained to the boy and he rapidly accepted the fact that there was need for a greater food intake, but he went to the extreme and ate huge quantities of food, so that he vomited at times. His weight showed a progressive increase; twenty-four days after admission it had risen to 92 pounds (42 Kg.). The basal metabolic rate was then -27 per cent. With the greater intake of food there was a low-grade fever ranging up to 100 F., lasting three weeks. During the next five weeks the intake of food was more moderate and there was but little change in weight. On discharge from the hospital, nine weeks after admission, his weight was 94 pounds (43 Kg.) and his basal metabolic rate -29 per cent. It was arranged that he should be sent to a boarding school to get him away from the home environment. Improvement was uninterrupted and the patient did well at school, mixing with the other boys and showing no return of his former symptoms.

The diagnosis was between schizophrenia and anorexia nervosa. It was felt that the latter diagnosis was the more likely in view of the rapid response to treatment in the hospital away from the home environment.

The patient was seen April 11, 1938. He was feeling well and seemed active and happy. His height was 5 feet 11 inches (180 cm.), his weight 159 pounds (72 Kg.), the basal metabolic rate -8 per cent. He was then 17 years of age and normally developed.

CASE 5.—M. A., a girl aged 16, was admitted to the hospital Sept. 24, 1934, complaining of amenorrhea of eighteen months' duration. Menstruation had commenced at the age of 11 and had been essentially normal until twenty months previously, when, after being scanty for two successive periods, it ceased entirely. She said that she felt well but that her appetite had been poor and that she had suffered from constipation for several years. She had been taking 1 grain (0.065 Gm.) of desiccated thyroid daily for one year.

The patient was emaciated; her height was 5 feet 5 inches (165 cm.), weight 91 pounds (41 Kg.), blood pressure systolic 95, diastolic 60, basal metabolic rate -28 per cent, pulse rate from 45 to 70 per minute, temperature from 96 to 98 F. The dextrose tolerance curve rose from an initial low level of 68 mg. to a peak of 220 mg., reached at the end of three hours (table 1). Repeated a few days later, the curve was lower (table 1). A barium sulfate enema showed tonus and haustration of the colon lacking to a moderate degree throughout. There was no anemia but the white blood count was 2,400, lymphocytes 31 per cent.

It was ascertained on enquiry that the patient weighed 135 pounds (61 Kg.) at the age of 11 and became very self conscious about her weight. The other children called her "Fatty," which annoyed her and evidently provided a basis for her curtailment of food intake since that time. She had always been very intelligent but inclined to fantasy. From the age of 4 she would occupy her time writing poetry, sketching and reading. She was always at the head of her class at school. She admitted day-dreaming a great deal since the age of eleven and preferred solitude to the company of others. She stated that people annoyed her and that she found talking an effort. At various times she tried to increase her food intake, but this would result in a bloated feeling in the abdomen, which she attributed to constipation. Enquiry revealed that the constipation was associated with faulty habits and that she was relying on frequent laxatives. The patient stated that her home life was a happy one except for the attitude of her older sister, who was continually taunting her, making reference to the desirability of having a good figure and with this in view making a study of food values and diets. The sister was not fat and the patient thought her unreasonable to diet. The patient

said that she had become acutely conscious of what other people ate. It would worry her when thin people left food on their plates or when obese people ate large amounts. This became an obsession with her.

The diagnosis was anorexia nervosa.

While in the hospital she usually was optimistic and cheerful. She spent her time reading books on philosophy and doing fancy work. Constipation was quickly relieved by instruction in proper habits and administration of liquid petrolatum. She was given a diet of 2,500 calories daily with 10 units of insulin one-half hour before the midday and evening meals. No thyroid was administered while she was in the hospital. Soon she took most of the food offered and on discharge was taking approximately 2,300 calories a day. Her weight increased gradually to 102½ pounds (46.5 Kg.) over a period of eight weeks and her mental attitude steadily improved.

Following discharge from the hospital Nov. 10, 1934, she resumed thyroid therapy and took 1 grain (0.065 Gm.) of desiccated thyroid daily until March 1936. The failure of this treatment to affect the basal metabolic rate materially is shown in table 2. Seen in December 1935, she was in good spirits, eating well and weighed 119 pounds (54 Kg.), but the menses had not yet returned. In May 1936 she weighed 150 pounds (68 Kg.), having gained 24 pounds (11 Kg.) in two months. Thyroid had been discontinued five weeks previously. The basal metabolic rate was now -17 per cent, the temperature 97.6 F., the pulse rate 54 per minute. The menses returned at this time and have continued normally ever since.

At present (May 1938) she feels well but is inclined to be nervous and easily upset. She is attending the university, working hard and doing well in her studies. Her height is now 5 feet 5¼ inches (165 cm.), weight 139 pounds (63 Kg.), basal metabolic rate -17 per cent, blood pressure 104 systolic, 68 diastolic.

CASE 6.—I. A., a woman aged 25, admitted to the hospital Nov. 22, 1935, complained of loss of weight, strength and energy, with increasing fatigue during the previous year. For several months she had noted swelling of the lower extremities and abdomen and frequency of micturition, latterly associated with thirst. She had not menstruated since 17 years of age, at which time she weighed 102 pounds (46 Kg.), her greatest weight. She had always been a small eater and disliked many foods, which included those of high caloric value. Because of attacks of frequency of micturition her physician had placed her on a markedly restricted diet, to which she attributed the rapid loss of weight.

Her home conditions were bad, her family being on relief. She lived alone with a semi-invalid mother, her father and a sister having died in recent years. The patient did all the housework.

The patient was extremely emaciated and pale; her weight was 69 pounds (31 Kg.), her height 5 feet 1½ inches (155 cm.). The secondary sexual characteristics were normally developed; head and body hair were abundant. There was edema of the feet, legs and thighs, and slight puffiness around the eyes. The hair and skin were dry. The temperature was from 96 to 99.7 F., heart rate from 70 to 90 per minute, blood pressure 74 systolic, 56 diastolic, hemoglobin 52 per cent, red blood count 3,000,000, white blood count 2,600. The twenty-four hour output of urine was approximately 500 cc. daily, with specific gravity relatively fixed between 1.010 and 1.1014. Albumin was present occasionally in small quantities. The non-protein nitrogen was 35 mg. per hundred cubic centimeters of blood, serum protein 3.5 per cent, the basal metabolic rate -32 per cent. The sugar tolerance curve was low and tended to be flat (table 1). Electrocardiogram, voltage 6 mm.

The diagnosis was anorexia nervosa. It was believed that the edema and anemia were secondary to prolonged malnutrition.

During the one week the patient remained in the hospital she was uncooperative, refusing to eat an adequate amount of food, and was resentful and complaining in her attitude toward her attendants and visitors. Finally she went home against advice. On readmission a few weeks later the edema was more marked and the mental attitude worse. Her weight was 75 pounds (34 Kg.), the increase believed to be due to edema. The

serum protein was 4.5 per cent. The average caloric intake for one week was about 1,100 calories a day. Again she went home against advice.

At present (May 1938) she is working as a domestic outside the city. Her mother believes that she is well. Her weight is now 125 pounds (57 Kg.). The menses are still absent.

CASE 7.—R. P., a woman aged 21, admitted to the Psychiatric Hospital March 31, 1936, complained that she could not eat, was tired all the time, and that she cried a great deal. She stated that at about 8 years of age she commenced to become stout. At 13 years she weighed 160 pounds (73 Kg.). Menstruation commenced at this time and was associated with considerable pain. The periods had never been very regular and stopped completely two years before admission. She became very conscious of her stoutness, especially of her large abdomen. Everybody teased her and called her "Fat." She had previously enjoyed swimming but about this time she noticed that her limbs felt numb and weak. She commenced to diet and from then onward lost weight. At the age of 16 she weighed 130 pounds (59 Kg.) but people continued to tease her. At 17 years of age she became nervously upset because of fear that she might fail in her matriculation examinations. Since that time she had been subject to nervous symptoms and had existed in a state of mild chronic ill health. About one year before admission to the hospital she commenced to cut down her food intake to a marked degree. She lost weight rapidly and became increasingly easily fatigued. Little things at home bothered her and she lost all interest in reading and knitting, which she had enjoyed formerly.

Examination was essentially negative, apart from the marked generalized emaciation. Secondary sexual characteristics were normally developed. Her weight on admission to the hospital was 77 pounds (35 Kg.), her height 5 feet 5 inches (165 cm.), the basal metabolic rate -26 per cent. The sugar tolerance curve was flat (table 1).

During her stay in the hospital the patient showed considerable variability in mood, at times displaying great apprehension and tearfulness and at other times being interested and cheerful. It was ascertained that there was a family background of religious fervor and that the mother was an emotionally unstable type of person and overly solicitous about the patient.

The diagnosis was anorexia nervosa.

The nature of her condition was explained to the patient and she was encouraged to eat an adequate diet. She cooperated well in this regard and engaged actively in occupational therapy. By April 14 her weight had increased to 81 pounds (37 Kg.). She was feeling much better and showed a decided improvement mentally. She was bright, enthusiastic and interested in her progress. However, she was anxious to leave the hospital and was discharged April 18 to go and stay with her sister-in-law. Information received May 1, 1936, indicated that the patient adjusted herself well after leaving the hospital and was eating fairly adequate meals. The improvement continued and in June 1938 it was ascertained that she was well and happy. She has been working for two months as a dress designer. She is well developed physically, weighs 110 pounds (50 Kg.) and is still gaining weight. The menses have not yet returned.

CASE 8.—S. A., an active alert, highly sensitive, wilful girl of 23, an only child, had fairly good health prior to 1934, at which time she weighed 112 pounds (51 Kg.). Rather unhappy at the university, she gradually lost to a weight of 94 pounds (43 Kg.) by the spring of 1936. She stated that during the preceding year the mistress of her boarding house had spread malicious tales about her carelessness of her health and refusal to eat. She felt this very keenly. Her appetite became worse and she began to vomit after eating without any associated nausea or discomfort. Her weight fell to 69 pounds (31 Kg.) by February 1937. The menses occurred three times in the year 1935-1936. She has not menstruated since September 1936.

In February 1937 she was emaciated, active, alert and intelligent and stated that she felt well. The secondary sexual characteristics were normally developed. The blood pressure was 80 systolic 58 diastolic, the basal metabolic rate -18 per cent, the fasting blood sugar 134 mg. per hundred cubic centimeters; the sugar tolerance curve was incomplete but appeared to be flat (table 1).

The diagnosis was anorexia nervosa.

The patient refused to come into the hospital. She went home, where she was unhappy, tried numerous types of therapy and is now worse than ever. Her own physician reports her weight to be 59 pounds (27 Kg.), her blood pressure 112 systolic, 60 diastolic. He states that, though she claims to be feeling better, she is extremely emaciated and looks sick. She refuses to come to Toronto, fearing that she may be kept in the hospital.

COMMENT

It would appear that anorexia nervosa occurs almost entirely in people of psychoneurotic constitution. Most of them are intelligent, some to a marked degree; all are highly sensitive. Usually they are impulsive, wilful, introspective and emotionally unstable, but these qualities may not be very obvious. Associated with a sense of inferiority, they have a strong desire for prominence and dominance. Usually they are alert and optimistic but are resentful of control on the part of their family. Prior to the onset of anorexia they are often good mixers but with its development they frequently become seclusive. In only two cases did we obtain a history of a psychotic trend dating from childhood.

In persons with such a temperament as a basis, prolonged emotional disturbance may precipitate the development of this peculiar syndrome, which appears most commonly in the unstable period of adolescence and early adult life. In most of our cases there was an underlying discontent as the result of a failure of adaptation to the domestic situation. In four patients (2, 4, 5 and 7) the taunts of companions about a conspicuous obesity led to a psychological repugnance for food which became a fixed habit. In others (cases 1 and 3) a morbid concern about minor symptoms referable to the gastrointestinal tract gave rise to a fixed fear of eating. In none did an acute emotional crisis precipitate the onset of symptoms. In only one case (case 6) was there a suggestion that therapeutic dietary restriction was a factor in the development of the condition. The other seven cases were definitely of the primary type. In none of our cases did we find evidence of any organic disease which might have been responsible for the symptoms.

The anorexia was peculiar in that it was not a simple want of desire for food such as is characteristic of wasting diseases but rather a morbid aversion to eating. It might be based on an abnormal desire to become thin, a desire to attract attention or gain sympathy, or a fixed belief in the inability of the stomach to hold any quantity of food (case 3) or a fear that ingestion of food would cause distressing symptoms. After a time this morbid anorexia became the habitual anorexia of undernutrition and starvation. It is evident that the morbid anorexia is a manifestation of an underlying psychologic disorder. It should not be attributed to a secondary disturbance in function of the anterior lobe of the hypophysis or any other endocrine gland.

Amenorrhea.—In the six female patients, as well as in many others reported in the literature, amenorrhea was an early symptom. It was present usually before the anorexia became marked and always before emaciation was extreme. In four of our cases the menses returned when improvement in nutrition and sense of well-being became well established. Neither of the other two patients cooperated but one has improved definitely in other respects, the other not at all. In no case was amenorrhea associated with loss of secondary sexual characteristics; the breasts remained wonderfully well developed, and axillary and pubic hair persisted in

all. In reporting his fatal case, Lockhart⁶ emphasized the fact that the breasts alone were not involved in the extreme generalized wasting. Libido is not grossly disturbed, although the state of chronic ill health may temporarily depress it. There is no atrophy of the external genitalia nor, as far as could be determined from examination, was there atrophy of other sexual organs.

It is generally recognized that change of environment and emotional disturbance may give rise to amenorrhea in apparently healthy young girls. Similarly, amenorrhea may be associated with many illnesses and with undernutrition⁴ in the absence of any demonstrable endocrine lesion. In some females the cycle appears to be easily interrupted, but little is known about the mechanisms by which this disturbance is brought about. When there is no other evidence of sexual dysfunction, it seems unreasonable to attribute the amenorrhea of anorexia nervosa to a gross disturbance in function of the adenohypophysis.

Low Basal Metabolism.—In anorexia nervosa the basal metabolic rate is usually reduced, sometimes to very low levels. The reduction may be more apparent than real because of the inadequacy of normal standards for emaciated adolescents. The lowering of the basal rate is comparable to that observed in undernutrition from other causes and would appear to be secondary to the emaciation. In Simmonds' disease, on the other hand, the lowered rate, although aggravated by emaciation, is primarily the result of the underfunctioning of the thyroid gland secondary to pituitary insufficiency and, accordingly, it rises in response to thyroid therapy. In anorexia nervosa the basal metabolic rate rises toward normal with the improvement in nutrition. Although not necessarily parallel to the gain in weight. It is notable that in two of our patients (4 and 5) treated with desiccated thyroid 1 grain (0.065 Gm.) daily there was no obvious effect on the basal metabolic rate and no improvement in their general condition (see table 2).

Blood Sugar Level.—The blood sugar tolerance curves obtained in seven of the eight cases tended to be of two different types. Beginning at a relatively low fasting level, the curve might rise gradually to a peak between 170 and 220 mg. per hundred cubic centimeters at the end of two or three hours, failing to fall to the fasting level, i. e., the type of curve seen in healthy patients who have been starved or given a high fat diet for a few days;⁷ or it might be low and flat, as seen in healthy people who have been on a high carbohydrate diet or in some patient with chronic undernutrition,⁴ e. g. nontropical sprue. The two types might be seen in the same patient within a short time. Since it was not possible to control the many factors that may alter the dextrose tolerance, it seems wiser not to attach too great significance to variation in the curve. The fasting blood sugar was below 68 mg. per hundred cubic centimeters only once: patient 5 suffered from prolonged undernutrition with low serum protein and some generalized edema. Other fasting blood sugar readings in her case were 78, 59 and 69 mg. per hundred cubic centimeters of blood. It is noteworthy that, although the fasting blood sugar level tends to be low in anorexia nervosa, the fall is not to be compared with that frequently seen in Simmonds' disease, Addison's disease

7. Sweeney, J. S.: Dietary Factors That Influence the Dextrose Tolerance Test, *Arch. Int. Med.* 40: 818 (Dec.) 1927.

or hyperinsulinism, nor do the patients suffer symptoms of hypoglycemia. It would seem probable that the variations in carbohydrate metabolism are secondary to chronic undernutrition.⁸

DIFFERENTIAL DIAGNOSIS

Patients suffering from wasting diseases such as tuberculosis or tumors of various kinds are usually quite ill, complain of weakness and fatigue and have obvious physical signs long before they reach the degree of emaciation seen in patients with anorexia nervosa. The latter patients are characteristically restless and active, even when emaciation is extreme, and commonly they will not admit being ill. Their alarmed relatives bring them to the physician but the patients protest that they feel well.

Addison's disease is usually differentiated with ease by the characteristic weakness, pigmentation, crises of nausea and vomiting, and low blood sodium. In both conditions the blood pressure may be low. In Addison's disease there is no related fundamental psychologic disturbance, the anorexia is not a constant feature, and often emaciation is a late symptom. In one instance, however, an erroneous diagnosis of anorexia nervosa was initially considered in an emaciated adolescent with pigmentation. This diagnosis was doubted because no adequate psychologic disturbance could be found to explain the anorexia and soon great fatigue and weakness with crises of nausea and vomiting pointed the way to a correct diagnosis of Addison's disease.

As a result of modern interest in the pituitary gland many cases presenting the picture of anorexia nervosa have been reported in the literature as cases of Simmonds' disease (extreme insufficiency of the anterior lobe of the pituitary gland). Superficially the syndromes closely resemble each other. In both, emaciation is a striking feature.⁹ In both are found amenorrhea, lowered basal metabolic rate, altered sugar tolerance, low temperature and psychologic changes. On careful examination, one finds that the syndromes are fundamentally different.

Simmonds' disease occurs most commonly and most typically in adult women who have had several children and who have previously had ordinary good health. The disease usually begins in the puerperium after a difficult labor associated with sepsis, postpartum hemorrhage or some complication. It may occur also when the anterior lobe has been destroyed by tumor, granuloma or trauma. There is no underlying psychoneurotic constitution or any precipitating emotional cause. The syndrome of anorexia nervosa develops in adolescents and young adults and occasionally in older persons who have a psychoneurotic tendency. Precipitated by an emotional disturbance, it is cured by psychotherapy.

As already mentioned, the anorexia of anorexia nervosa is a morbid aversion to eating, whereas in Simmonds' disease there is loss of appetite unassociated with emotion. In both, emaciation develops and with emaciation comes the appearance of senility, which however tends to be more marked in Simmonds' disease. The amenorrhea of Simmonds' disease is associated with loss of sexual function, loss of secondary sexual characteristics, falling out of axillary and pubic hair, and atrophy of the sexual organs. It persists

unchanged in spite of therapy. In anorexia nervosa, amenorrhea occurs as a single symptom, important chiefly because of the concern it gives the patient and the patient's relatives, and not associated with other evidences of failure of sexual function.

The basal metabolic rate in Simmonds' disease is usually lower than in anorexia nervosa. Being due largely to underfunction of the thyroid gland, it responds more readily to the administration of small doses of thyroid than does the lowered rate of anorexia nervosa, which is secondary to emaciation. The blood sugar in Simmonds' disease is lower than in anorexia nervosa, and attacks of spontaneous hypoglycemia are common. In Simmonds' disease there is almost always anemia of moderate severity, which is unusual in anorexia nervosa.

Most striking is the difference in mental status. In Simmonds' disease the patient is dull and apathetic and shows intellectual impairment and usually gross changes in personality. In anorexia nervosa the patient is generally quick, alert, restless and intelligent but may become wilful, sensitive, impulsive and hysterical. Only in rare cases with gross psychotic manifestations does the mental state in anorexia nervosa in any way resemble that of Simmonds' disease.

The characteristic pathologic change in Simmonds' disease is an almost complete destruction of the anterior lobe of the pituitary gland with secondary atrophic changes in other endocrine glands, viscera and skin. There are few reports of postmortem examination in cases of anorexia nervosa and the description of the endocrine glands in these is incomplete.¹⁰ The available data suggest that there is no characteristic change in the endocrine glands. This opinion is supported by the unpublished detailed observations in a recent fatal case that has been brought to our attention. If anorexia nervosa were a "functional Simmonds' disease" there should be characteristic secondary changes in gonads and other endocrine glands.

The improvement in cases of anorexia nervosa, reported as such or as Simmonds' disease, has often been ascribed to the effect of administration of various endocrine preparations: insulin, thyroid, various female sex hormones and various pituitary preparations. Improvement occurring after pituitary therapy has often been taken as evidence of the correctness of the diagnosis of pituitary insufficiency (case 1). Actually the use of such preparations may be an effective, but not the most desirable, method of psychotherapy.

TREATMENT

The aims of treatment are to change the attitude of the patient toward food so that emaciation will be relieved through the ingestion of an adequate diet and to insure permanent recovery by eradication of the underlying mental conflict. The former often can be attained by change of environment, encouragement and suggestion, but if the second objective is to be realized the psychologic basis must be discovered and remedied if possible. Prolonged psychotherapy is often necessary before the patient fully understands the true nature of his illness and especially the effect that various environmental factors, past and present, have had on its development. This understanding is essential if the patient is to become properly adjusted to those disturbing associations in his daily environment from which there is no escape.

9. It is true that emaciation may be lacking in Simmonds' disease, but this is exceptional.

10. Elliott, T. R.: Pathological Changes in the Adrenal Glands, *Quart. J. Med.* 8: 47, 1914. Conybeare, J. J.: A Fatal Case of Anorexia Nervosa, *Guy's Hosp. Rep.* 80: 30 (Jan.) 1930. Lockhart.

On commencing treatment it is desirable that the patient be removed to a hospital away from overly solicitous relatives and friends. Treatment in the public ward is to be preferred, because contact with other patients suffering from various organic diseases has a salutary effect on most patients with anorexia nervosa and makes the reassurance they receive more gratifying and significant. The well ordered routine of a hospital, the optimism of doctors and nurses and the evidence of recovery around them all have therapeutic value which, combined with freedom from the stress of their former environment, often results in rapid and striking improvement. To obtain the best results from psychotherapy it is essential that it be preceded by a most careful and thorough investigation of the patient. This is important both for the confidence it gives to the physician and for the reassurance of the patient. The life history of the patient should be obtained, with particular emphasis on his emotional reactions to his associates. The factors at the basis of the neurosis are sometimes quickly revealed, but often cooperation is imperfect and it is necessary to persevere in the search by questioning the patient's relatives and friends. Discussion should be continued until the patient understands clearly the connection between the psychologic maladjustment and the development of his symptoms.

The patient should be reassured with the utmost confidence that no organic basis for the symptoms exists and he should receive an explanation of the relationship between emotional disturbances and the imbalance of the autonomic nervous system which may result. The manner in which the stomach adapts itself to gradual and persistent lessening of the food intake should be explained so that the patient's apprehension over the feelings of fulness which occur when he tries to increase his intake can be allayed.

The patient should be encouraged to eat, at frequent intervals, small but gradually increasing quantities of food of high caloric value. The caloric intake should be carefully calculated daily, and praise and encouragement given with each increase that occurs. When about 3,000 calories is being taken daily and gain in weight is evident, the frequency of the meals can be gradually lessened and the variety of food increased.

In some cases feeding by duodenal tube may be necessary in the early stages of treatment but usually the method outlined is all that is required. Insulin to stimulate the appetite should not be used except as a last resort. Similarly, nonspecific endocrine therapy should be avoided, because permanent results are more likely to be obtained if no artificial aids are employed.

During the patient's stay in the hospital every effort should be made to divert his thoughts from his obsession. The public ward is obviously more effective than a private room for this purpose. Occupational therapy is of great assistance, particularly if the hospital has a workshop available where skilful therapists may introduce a spirit of friendly competition with certain other patients in some work or game. By this means a feeling of achievement may be engendered which will go far to restore the confidence these patients need so badly and thus facilitate recovery.

SUMMARY

The eight cases of anorexia nervosa that we have reported present the typical syndrome of emaciation, amenorrhea, low basal metabolic rate, low blood pressure and often rather low fasting blood sugar values

with flat sugar tolerance curve. Although the syndrome bears a superficial resemblance to that of Simmonds' disease, it is actually quite distinct and different.

The syndrome of anorexia nervosa develops as a result of an underlying mental conflict and appears usually in the unstable period of adolescence, most commonly in intelligent girls whose emotional constitution and autonomic nervous control are unstable.

These patients respond well to proper psychotherapy. If the cooperation of the patient and the family can be obtained, cures should be effected for all patients placed in a suitable environment with the exception of those who have serious mental disease.

There is no specific endocrine therapy for this condition, but these patients being of a hysterical nature will often respond temporarily to the suggestion that goes with confident administration of a special extract. Actually such treatment should be avoided because permanent results are more likely to be obtained if no artificial aids are employed.

Clinical Notes, Suggestions and New Instruments

UNDULANT FEVER TREATED WITH SULFANILAMIDE

E. F. TRAUT, M.D., CHICAGO, AND CATHARINE ELIZABETH LOGAN, M.D.,
OAK PARK, ILL.

Sulfanilamide was originally found successful in the treatment of infection produced by gram-positive organisms. It is also effective in controlling infections due to gram-negative bacteria.

Berger and Schnetz¹ used it in the management of brucellosis. Stern and Blake² report three cases in which cure resulted with the drug. They were apparently unaware of its previous use in brucellosis, since they gave no bibliography. Working independently, we had found it beneficial in two cases of undulant fever. Our report, submitted to THE JOURNAL in January 1938, was rejected and returned in April. Sulfanilamide was furnished to us by the Winthrop Chemical Company.

CASE 1.—H. K. worked in the stockyards as a truck driver, handling both raw pork and beef. He entered Cook County Hospital in April 1937. Before admission he had been sick three weeks with chills, fever, sweating, generalized aching and weakness. His temperature continued to fluctuate between 98 F. in the early morning and 103 F. in the afternoon in the hospital as it had at home. The leukocytes numbered 6,800. The spleen was palpable. The Widal reaction was negative. Cultures of the blood and urine gave negative results. On admission his serum agglutinated the bovine and porcine forms of *Brucella melitensis* through 1:320 on the slide and above 1:1,280 in the test tube.

Stock vaccines of the porcine and bovine forms of *Brucella melitensis* were given twice a week for three weeks without benefit. Three weeks later sulfanilamide was started. Twenty-four hours after he received eight tablets his afternoon temperature was lowered and after forty-eight hours it was normal and remained so. The sulfanilamide was stopped one week later. During his remaining stay of one month his temperature did not exceed normal. He regained strength and appetite. He has remained well.

CASE 2.—A woman aged 69 became ill in Florida with chilliness and fever but no rigors. Periods of fever, interrupted by intervals of normal temperature, continued for eight weeks. During this period her weight decreased from 125 pounds to 65 pounds (56.7 to 29.5 Kg.). She had wandering pains in the

2. Stern, R. L., and Blake, V. W.: *Undulant Fever: Its Treatment with Sulfanilamide*, J. A. M. A. 110: 1550 (May 7) 1938.

joints. The hemoglobin content decreased to 50 per cent, the red blood cells to 2,500,000 and the leukocytes numbered 3,000. The sedimentation rate was rapid. Repeated searching yielded no plasmodia. There were no intestinal parasites. *Brucella melitensis* bovinum was isolated from the blood and her serum in a dilution of 1:15,000 rapidly agglutinated *Brucella melitensis*. At the end of eight weeks she was jaundiced and went into a stupor. She had a blood transfusion at this point, and 30 grains (2 Gm.) of sulfanilamide (prontylin) was given daily. Within forty-eight hours she was free of fever. She has remained afebrile to this date, twelve months later.

Sulfanilamide effected prompt and apparently permanent cures in two patients with brucellosis.

TICK PARALYSIS DUE TO THE BITE OF THE AMERICAN DOG TICK

REPORT OF A CASE OBSERVED IN GEORGIA

MEINHARD ROBINOW, M.D., AND T. B. CARROLL, M.D.
AUGUSTA, GA.

Until recently little attention had been paid to a type of ascending paralysis of the flaccid type caused by the bite of certain ticks. The disease has been observed in children and in the young of animals, especially sheep and dogs. Adult human beings and mature animals are rarely afflicted.

The literature contains several excellent works on the condition from which the symptoms and the course of the disease in man can be studied.¹ Premonitory symptoms such as paresthesias, pain in the legs, dizziness, restlessness and general malaise may or may not be present. They may precede the paralysis by several days. The onset of the paralysis is characterized by its sudden appearance and rapid progress. Muscular weakness and asynergia appear first, followed in a few hours by more or less complete flaccid paralysis beginning in the lower extremities and extending upward, involving the arms and the neck. Speech and deglutition become difficult, the pupils dilate and in untreated cases death from respiratory paralysis supervenes.

The diagnosis is made from the clinical symptoms and the finding of an engorged female tick on the patient's body, most commonly on the scalp. Early removal of the tick is followed by rapid recovery, which is usually complete within three days. Failure to remove the tick or delayed removal leads in most if not all cases to a fatal termination.

Laboratory experiments² suggest that the disease is not caused by a living virus but by a venom which is elaborated in the developing ova of the impregnated female tick. Tick paralysis in children has been reported from Montana, Idaho, Washington, Oregon, Wyoming and British Columbia. Most cases occur in the spring and early part of the summer.

The tick responsible for all human cases reported in the United States and Canada is *Dermacentor andersoni* Stiles, the Rocky Mountain wood tick. This tick has attracted widespread attention as a vector of Rocky Mountain spotted fever, tularemia, relapsing fever and probably Colorado tick fever. Paraly-

sis seems to occur only after the impregnated female tick has fed for several days on a patient. Detailed information on ticks and tick-borne diseases may be found in a recent article by Parker and his associates.³ A similar disease in man caused by a different species of ticks, *Ixodes holocyclus*, has been reported from Australia.⁴ Tick paralysis in sheep, caused by *Ixodes pilosus* Koch, has long been known in South Africa.⁵ Recently, cases of paralysis in young dogs following the bite of *Dermacentor variabilis* Say, the American dog tick, have been observed in the eastern section of the United States.⁶ It is remarkable that ticks are common in many regions from which cases of tick paralysis have never been reported.⁷

We are reporting this case of tick paralysis for two reasons: 1. This case was observed in Georgia. No cases east of Wyoming have been reported previously. 2. Recovery followed the removal of *Dermacentor variabilis*, a tick which has not been known to cause paralysis in children.

REPORT OF CASE

A white girl aged 9 years of Hepzibah, Ga., was first seen in the emergency room of the University Hospital June 19, 1938, at noon. The mother related the following history: The birth and development of the child were normal. She had whooping cough at the age of 9 months and scarlet fever at the age of 7 years. The parents and four other children were in good health. One of the children had had infantile paralysis several years before.

During the past week the patient had been complaining of feeling weak. On awakening on the morning of admission she was unable to get out of bed and complained of pain in the

Distribution of *Dermacentor variabilis* in the United States. Large dots indicate localities where collections were made by the Bureau of Entomology and Plant Quarantine; small dots indicate the probable range. (Reproduced from Bishop and Smith.⁹)

left thigh. She was carried to the breakfast table. There it was noticed that the arms moved in an incoordinate manner. She was unable to feed herself, and her left hand dropped into a bowl of hot food. She sustained a burn on the wrist but did not seem to experience any pain.

On admission the child appeared acutely ill. The temperature was 100.6 F. There was flaccid paralysis of both legs with absence of the tendon reflexes. The arms were weak and showed marked asynergia. The biceps and triceps reflexes were present. There was no difficulty in swallowing but the speech was thick and drawling. The eyes showed marked lateral and vertical nystagmus. The pupils were normal in size and reacted promptly to light.

7. Barnett,¹ Parker, Philip, Davis and Cooley.³

Poliomyelitis or poliencephalitis was suspected and a diagnostic spinal puncture was performed. Clear fluid was obtained under pressure of 10 mm. of mercury.

Examination of the spinal fluid showed cell count 3, negative Pandy and Ross-Jones tests, total protein 50 mg. per hundred cubic centimeters, colloidal gold test 0000000000, and the Wassermann and Kahn reactions were negative. Cultures yielded no growth.

Analysis of the blood revealed red blood cells 4,800,000, hemoglobin 82 per cent, white blood cells 8,400, differential count: polymorphonuclears 72 per cent, eosinophils 0, basophils 0, lymphocytes 28 per cent, monocytes 0.

Urinalysis showed albumin none, sugar none, acetone none; microscopic examination revealed from 15 to 20 white blood cells per low power field.

Examination of the stool gave negative results for blood, parasites and ova.

The Wassermann, the tuberculin and the Schick test all gave negative results.

Soon after admission two ticks were found attached to the scalp in the parietal region. One of these was markedly engorged. They were carefully removed. The presence of the ticks had not been noticed by the patient or her parents, although a large ecchymotic area was present at the point of attachment. The diagnosis of tick paralysis was now made and the further course of the illness seemed to justify the diagnosis.

The ticks were identified as *Dermacentor variabilis* Say.⁸ The large engorged tick was a female, the smaller one a male.

At 6 p.m. the patient showed considerable improvement. The speech had become almost normal. Ataxia of the arms and legs was now the prominent symptom, while muscular strength had greatly improved. Further improvement was evident the next morning. The knee and ankle reflexes had returned and the patient was able to stand unsupported. Walking was still difficult and the Romberg sign was markedly positive.

On June 23 another tick was found on the scalp and was removed. This tick was a female which did not show any signs of engorgement. At this time the patient appeared almost normal. Recovery was complete June 24, and the patient was allowed to leave the hospital. The last symptom to disappear was some slight difficulty in walking, which seemed to be caused by ataxia rather than by muscular weakness.

COMMENT

The clinical symptoms, the finding of the ticks and the rapid recovery following the removal of the ticks seem to establish the diagnosis beyond doubt. We believe that this case is of considerable interest. The American dog tick is a common parasite which is widely distributed in the eastern parts of the United States, as shown in the chart. It frequently attacks man.⁶ Since the tick is known to cause paralysis in dogs, it is a priori probable that it can also cause paralysis in children. Similar cases may have occurred in other states but not been recognized, since the disease may easily be mistaken for other types of paralysis, poliomyelitis or poliencephalitis. The importance of diagnosing the condition is obvious since the outcome depends on the early removal of the ticks.

SUMMARY AND CONCLUSIONS

1. A case of tick paralysis in a 9 year old girl was observed in Augusta, Ga. Rapid recovery followed the removal of a male and an engorged female dog tick.
2. Tick paralysis in a child caused by the American dog tick has not previously been reported.
3. The American dog tick is a common parasite in many parts of the United States. It is suspected that other cases have occurred which have been mistaken for infantile paralysis.

8. Dr. E. H. Ewing from the Division of Insect Identification, Department of Agriculture, Washington, D. C., and Dr. R. C. Dienst from this school identified the ticks, and Dr. E. C. Cushing, Department of Agriculture, and Dr. R. R. Parker, director, of the Rocky Mountain Laboratory, U. S. Public Health Service, Hamilton, Mont., contributed valuable information.

MENTAL HYGIENE AS RELATED TO THE PSYCHONEUROSES

CLINICAL LECTURE AT SAN FRANCISCO
SESSION

WILLIAM E. GARDNER, M.D.

Clinical Professor of Psychiatry, University of Louisville School
of Medicine

LOUISVILLE, KY.

Mental hygiene is now accepted not as a theory of human behavior, as erroneously referred to by many in the early days of its development, but as a movement, in a broad sense, for improving the care and treatment of the mentally ill, preventing mental disorder and preserving mental health. With these crystallized purposes it had its inception in this country in 1908 at the organization of the Connecticut Society for Mental Hygiene by Mr. Clifford W. Beers. In the following year Mr. Beers founded the National Committee for Mental Hygiene, of which he became the first secretary, which position he has held continuously up to the present time. Many are familiar with the colorful life of Mr. Beers and his outstanding achievement in having been able to enlist and hold the interest and support of numerous influential citizens of America, both lay and professional. Among the latter are such names as August Hoch, Frederic Peterson, Lewellys F. Barker, the late Drs. William H. Welch and William Alanson White, and perhaps the most prominent of those still living and actively interested, Dr. Adolph Meyer, the acknowledged dean of psychiatry of the present generation. These, along with many prominent laymen of large means and succeeding groups of professional people, have given either substantial amounts of money or technical counsel in the initiation and development of a movement which has grown into one of the most valuable agencies for human welfare.

The early interests of the National Committee for Mental Hygiene were centered on the improvement of the care and treatment of the mentally ill in public hospitals. Numerous surveys were made of the physical equipment and treatment facilities of such institutions in various states, and recommendations followed which brought about reforms of inestimable value. This influence gradually extended to private hospitals for the care of the mentally ill, with corresponding improvement of service in these hospitals. Then followed the development of agencies for the ostensible purpose of preventing mental disorders, both in the form of mobile clinics in connection with various state hospitals and in the establishment of psychologic and psychiatric examinations of children in public schools and the outpatient departments of general hospitals. Much of this early pioneer work had been accepted as valuable, and in order to help various communities achieve their purpose in a preventive program the Commonwealth Fund in 1922, under the guidance of the National Committee for Mental Hygiene, established demonstration child guidance clinics in seven of the largest cities. Within six years thereafter more than 500 mental hygiene clinics had been organized in this country, and on Jan. 1, 1936, according to the Directory of Psychiatric

Read in the General Scientific Meetings at the Eighty-Ninth Annual Session of the American Medical Association, San Francisco, June 12, 1936.

Clinics published by Dr. George S. Stevenson,¹ director of the Division on Community Clinics, there were in thirty-nine states 684 clinics of this type, supported either by private or by public funds, including those associated with medical schools and outpatient departments of general hospitals.

The emphasis, in the early days of child guidance clinics, was on the prevention of mental illness and delinquency, by personality studies and educational measures, in order to forestall later hospitalization or penalization. More recently there has been a shift of emphasis from the thought of future psychoses or criminal careers to the need of psychiatric attention for the child's own sake, in an effort to enhance his feeling of security and to obtain for him a better social adjustment. In line with this later and present day trend, attention is quite naturally directed to that tenet of the mental hygiene movement which embraces one of its most practical phases, the preservation of mental health. While the prevention of mental illness and the preservation of mental health may appear, on the surface, to be synonymous, one can never know just how much has been accomplished by so-called methods of prevention, owing to the belief that there are so many obscure and deep seated forces at play which may act as predisposing factors in the production of mental illness, especially the major forms of maladjustment, usually designated as psychoses. I have in mind, particularly, the inescapable influences of heredity and constitutional predisposition which affect the lives of all persons in their mental and emotional adjustments and which have been transmitted not solely from the immediate ancestors but from those of many preceding generations. The total personality makeup may therefore be thought of not only as that which has been built up and organized in the process of development of the individual but as an outgrowth of his historical past, as well.

When we come to the precipitating circumstances of mental illness, nearly all psychiatrists are in agreement that their concepts are somewhat more tenable. Herein lies their greater hope, by the improvement of methods of diagnosis and the application of special skills in treatment to the degree that, in at least a fair but unknown percentage of cases, major psychotic manifestations may be actually forestalled. These are worth while and laudable concepts and constitute a goal toward which all of us strive. They are the foundations of much of the mental hygiene movement.

THE PSYCHONEUROSES

Thus far I have discussed in a general way some of the broader purposes of the mental hygiene movement and now come to that phase of the subject more specifically related to the title announced; namely, a consideration of the psychoneuroses. For purposes of convenience and relative simplicity, a psychoneurosis may be defined as a condition in which an individual reacts to an unhappy or threatening situation by a group of symptoms which have an instinctive basis and which are manifested in the form of various escape and defense reactions distinctly different from those of the general population who are, at least for the time being, sufficiently integrated in their personality makeup that they can face similar situations more frankly than one suffering from a psychoneurosis is capable of doing. The one has a tendency to regress to a primitive or

infantile type of behavior, governed by an instinctive drive, and the other to act on a more rational basis. The former does not, however, have a type of behavior that is incompatible with sanity and responsibility, and such an individual is usually in sufficient contact with reality that he is thought of by his associates as being essentially normal.

In most textbooks on psychiatry there is a tendency to include all neuroses and psychoneuroses under the general classification of the latter, whereas those who have approached a study of these borderline states of maladjustment from the psychoanalytic point of view have designated the neuroses as the more inclusive term. Their classification has been favorably received by many psychiatrists and neurologists who have endeavored to obtain a better understanding of the origin of the mental mechanisms that underlie the symptom formation in this large group of cases, although many of them, as well as myself, have not attempted to use formal psychoanalysis as a therapeutic procedure. Wechsler,² who has compressed the principles of the latter classification into a few simple paragraphs, makes the following statement:

Freud divides the neuroses into Actual Neuroses and Psychoneuroses. By the former he means those neuroses in which, aside from the immediate or precipitating psychologic factor, there is actual, even if temporary, physical disturbance within the organism. In this group he includes anxiety neurosis, neurasthenia and hypochondria. Traumatic neurosis may possibly be added. By psychoneuroses he understands those neuroses which illustrate the various stages of regression to infantile points of fixation. The whole group is, therefore, known as Regression or Fixation Neuroses. Under this head are classed the Transference Neuroses, which include conversion hysteria, anxiety hysteria and compulsion neurosis.

It is furthermore stated that in the present state of our knowledge it is impossible to make a rigid classification on account of the difficulty of defining what is normal and that clinical observation reveals that mixed neuroses are extremely common. One does not always see pure anxiety or conversion hysteria, pure anxiety neuroses, pure compulsions and the like but conditions in which there is a little of each. Elaborating a step further, it is noted that the same mental processes are observed in the socially well adapted person as in the maladjusted neurotic. It can therefore be agreed that every normal person is a little neurotic and that every neurotic person is very much normal. It is only in the degree of variation in the conduct of individuals under similar social and other environmental influences that the need of investigating the motivation of psychobiologic processes may arise to account for what might be looked on, in a particular person, as neurotic behavior.

UNDERLYING FACTORS

Much knowledge regarding the underlying factors of neurotic behavior has been gained from the study of primitive people and children and from the behavior of animals. In fact, reactions of escape and defense are observed in the lower forms of animal life, striking examples of which are related by Ernst Kretschmer³ of Marburg in his discussion of hysteria, as follows:

If a swimming infusorian approaches a zone of heated water, it reacts with an overproduction of lively motions which continue until one of them takes it away from the dangerous area.

1. Stevenson, G. S.: *Directory of Psychiatry Clinics in the United States*, 1936, *Ment. Hyg.* 20: 66 (Jan.) 1936.

2. Wechsler, I. S.: *Clinical Neurology*, Philadelphia, W. B. Saunders Company, 1928.

3. Kretschmer, Ernst: *Hysteria*, Monograph 44, Washington, D. C., Nervous & Mental Disease Publishing Co., 1926.

whereupon it quietly swims away. If a bee or a bird is caught in a room, it will neither sit in one corner and deliberate, nor will it methodically examine the doors and windows for an opening, but, instinctively directed toward light, will release a violence of sprawling, fluttering, aimless to and fro jerky motions which are spasmodically repeated until one of them by chance carries it through an open window into freedom, after which the usual motions of flying are at once resumed.

Such methods of escape mechanism are referred to by Kretschmer as violent-motor-reaction. In living beings, it is stated, the violent-motor-reaction is a typical reaction to situations which threaten the course of life. It is a spontaneous reaction of biologic adaptation. In the course of evolution this type of reaction as a biologic defense mechanism assumes a place of relatively less importance. More expedient forms cover over the older reaction type. In apes there is a beginning of systematic search and deliberation, a more quiet and less motor type of reaction. In adult human beings, selective voluntary action becomes more noticeable, and only under conditions of peculiar stress will the violent-motor-reaction be observed. In cases of panic, for instance such as in an earthquake, a crowd of people will behave very much like an imprisoned bird. If among the many motions initiated there is one which by chance will take a person away from the danger zone, quiet at once ensues; the violent-motor-reaction has attained its purpose. The individual has achieved a gain through his biologic adaptation to a threatening situation.

Another group of instinctive reactions occurring in the lower forms of animal life, which exemplify a defense mechanism against threatening situations, has been referred to by Kretschmer as the sham-death-reflex. This is thought to have a close relationship to cataleptic and hypnoidal states. He refers to the work of Babak,⁴ who has done much research on fish, especially callichthys, and who illustrates the hypnoidal process, or sham-death-reflex, as follows:

If startled, the animal almost instantly changes from a black to a whitish or reddish color, rapidly moves his pectoral fins and, instead of fleeing, throws himself upon one side and remains in that position. In addition, there appears a certain amount of rigidity, the fins are spread, and the gill movements cease for a time. The animal may remain motionless for a quarter of an hour or more, and, to arouse it, one must often shake the animal strongly or push it farther under the water, whereupon the normal swimming movements will usually follow.

It is stated that similar reactions may be traced and studied all through the animal series. Kretschmer believes it is significant that this "animal hypnosis" prefers the same situations around which hysterical reactions in man are most frequently grouped; namely, danger to life and the business of reproduction. In the service of reproduction, he states, are seen examples of reflex immobility very well demonstrated in chickens.

Through the few examples that have been given, I have called attention to some of the biologic principles which underlie the formation of escape and defense reactions in the presence of threatening situations and briefly referred to the fact that, in adult human beings, selective voluntary action becomes more noticeable with the intricate and elaborate development of a personality makeup. More useful and expedient formations cover over the older reaction types. Through them all, however, is seen a similar tendency of the living organism to act in unusual or extraordinary ways in times of

stress. There is always a purpose to be fulfilled, whether it is instinctive and unconscious or in the twilight zone of consciousness and rationality. Such purpose is, at least, of temporary advantage both to the lower animals and to human beings. In the latter it is referred to as a neurotic reaction, and in most instances is a defense against or a flight from an unhappy inner experience.

The commonly designated pleasure-pain principle of analytic psychology means that all of us, either consciously or unconsciously, endeavor to seek that which is pleasurable and avoid that which is painful. In our effort to escape the painful and still preserve our self esteem, however, many unhappy inner experiences are sometimes relegated to the realm of the unconscious and deposited there as if they had never existed. Some of these which may, for months or even years, appear to have been permanently forgotten are surcharged with such emotional content, however, that an outlet is inevitable, and they will escape either in the form of disguised and distorted dreams or through neurotic and psychotic reactions. In other words, there is always present the instinctive or unconscious tendency to escape from the painful experiences of reality in times of stress. In lower animals this is exhibited in excessive activity of the pristine motor system, in the form either of violent-motor-reaction or of the sham-death-reflex; in human beings, by more highly developed, yet not dissimilar, psychobiologic reactions which have a definite, and sometimes dramatic, purpose in keeping the individual out of the zone of danger. From the psychiatric standpoint, a danger zone may be thought of briefly as a situation in which there is evidence of persistent emotional conflict, based on a deep seated anxiety and inadequate adjustment thereto, which threatens to carry a major portion of the human personality beyond the realm of conscious reality.

Repressed anxiety, which is the essential factor in the symptom formation of all the psychoneuroses, is usually the result of an unconscious sense of guilt, sometimes, though not always, based on a preexisting feeling of hatred or bitterness toward an individual or situation, secondary to the frustration of some selfish desire. Such anxiety is therefore closely related to unhappy inner experiences already referred to. Although repressed, anxiety never lies completely dormant and constantly craves some method of expression. If not released in psychomotor restlessness or similar forms of exaggerated emotional response, other avenues of escape will inevitably ensue. It may, by transference, appear in the form of various motor and sensory disturbances closely simulating organic disease and thus produce such somatic symptoms as will satisfy the self esteem of its host until other and more rational outlets are available. Anxiety has for the time being been converted into psychoneurotic symptoms which give at least partial relief of the inner tension and have therefore been of psychobiologic value to the individual. In fact, it is now believed by some that the development of a psychoneurosis may in many instances actually forestall the onset of a frank psychosis or even be the means of escape from suicidal impulses. I do not wish to give the impression of putting a premium on the psychoneuroses but offer no apology for calling attention to some of the benign characteristics of these disorders which, in their compensatory formations, have a tendency to preserve the integrity of the personality, an essential requisite of mental health.

4. Babak: Arch. f. d. ges. Physiol., 1917.

NEUROTIC TENDENCIES IN CHILDHOOD

Clinical statistics are not thus far easily available to show with any degree of accuracy what percentage of psychoneuroses in adults is an outgrowth of neurotic tendencies in childhood, since it is known that child guidance clinics in this country were not fully established on a broad scale in the larger cities until the end of the third decade of the present century. About the middle of the previous century, however, a London physician by the name of John Elliotson⁵ published articles on functional nervous diseases of childhood, pointing out that much that passed for naughtiness was indeed illness and that many children who showed anti-social tendencies were sick children whose place was in a hospital rather than in a reformatory. In the latter part of that century there was a still further development in the knowledge of nervous diseases, especially in Europe, and it was Sigmund Freud⁶ of Vienna who threw more light on these disorders in childhood. It was perhaps he who first called attention to the fact that the roots of functional nervous disorders of adults could be traced back to early years, when definite nervous symptoms had disturbed the life of the patient, although they had usually remained unrecognized by those attending the child. We are furthermore equally indebted to Pierre Janet⁷ of Paris for much of our knowledge of the principles which underlie the symptom formation of the psychoneuroses, especially in adults.

There has been some objection to the use of the term "neurotic child" on the ground that it is too general and vague and that it is used to denote widely divergent types of nervous disease. An effort to soften the term to "the problem child," "the difficult child," "the mal-adjusted child" removes the idea of illness still further, however, from the thoughts of those who have such children in their care and fosters a belief that the abnormalities displayed are evidences of temperamental awkwardness or social incompatibility. There are such traits, of course, but they are symptoms rather than the disease itself. A more valid objection to the word "neurotic" is that damage may arise from a too free use of the term. It has, aside from its medical sense, a popular use as an epithet of disdain. Parents may therefore resent the term, and even physicians are sometimes inclined to dismiss such a case as one for which there is nothing particular to prescribe except bromide, diet or fresh air. Many are still inclined to labor under the old misconception that "neurotic" means undisciplined, uncontrolled, naughty or badly brought up and to believe that if only the wayward child could be brought to see the error of its ways, and the parents taught to manage its education more skilfully, the problem would be adequately solved. It is becoming increasingly obvious, through the influence of the mental hygiene movement, that the treatment of nervous disorders in childhood is not so simple as that.

We sometimes hear the twentieth century referred to as the century of the child, and there is much justification for the statement. There has been a vast amount of progress in the improvement of facilities for his education, recreation and broader cultural achievement and for the protection and improvement of his physical well being. In close pursuit of this progress, facilities for the preservation of his mental health have been

greatly improved and enlarged. We are more conscious than ever before that the mentally healthy child of today will be the good citizen of tomorrow and for this reason more attention is being paid to the nervous disorders of childhood which may be related to psychoneuroses of later life. We are less concerned perhaps with behavior problems associated with mental deficiency, which are more easily recognized and the solution of which has been much simplified by well formulated methods of procedure. It has been learned, furthermore, that many of the common behavior problems of boys and girls are associated with slight deviations of personality reaction, which often occur in children of good intellectual and emotional endowment and when properly understood are recognized as being quite normal or at least average reactions to difficult interpersonal relationships or other disturbing environmental influences. In some cases there are physical disorders which have been overlooked and which are contributory to reactions of impatience, irritability or even rebellious conduct. One cannot therefore stress too much the importance of a thorough physical examination, with adequate laboratory studies when indicated, of the child whose happiness and efficiency appear to be seriously disturbed.

RECENT GROWTH OF INTEREST

Within the present decade, more particularly within the past five or six years, an increasing interest has been noted of the mental hygiene movement as related to the psychoneuroses through the influence of Dr. Franklin G. Ebaugh of Denver, professor of psychiatry, University of Colorado Medical School, and director of the Division of Psychiatric Education of the National Committee for Mental Hygiene. Dr. Ebaugh has within this time insisted that the departments of psychiatry of the medical schools of this country give more attention to the teaching of the psychoneuroses, and I am sure that he has been gratified by the favorable response to his suggestion. How much importance he attaches to an adequate understanding of these disorders is indicated by a chapter in his book,⁸ from which I quote:

The neuroses constitute the most frequent pathological situations encountered by the neuropsychiatrist. Their frequency is not reflected in statistics, since neurotic patients, although they make up the bulk of the clientele of neurologists and psychiatrists in private and in outpatient practice, nevertheless rarely seek treatment in public mental hospitals. The student should view the problem in the light of its tremendous social significance. If it could be reckoned, it would probably be found that the sum total of economic and social liabilities produced by the neuroses would be greater than the amount of damage inflicted on society by the psychoses.

While one cannot escape the conclusion, looking at the subject from a broad and unprejudiced point of view, that the psychoneuroses constitute a tremendous medical, social and economic problem, it should not escape attention that a large percentage of the most brilliant accomplishments in the fields of art, science and literature have been achieved by those who have had manifest neurotic tendencies, if not actual psychoneuroses. The same might be said of many of the outstanding leaders of commerce and industry, as well as of a host of others in the skilled professions. In other words, without citing prominent examples with which many are familiar, it would appear that the psychoneurotic individual has made a substantial contribution

to the social and economic progress of civilization; this by means of a strong impulse and peculiar vision which may be greater than that of others possessing equal intellectual and emotional endowment. He has given color to life in the variety of his achievement which has made him almost if not quite indispensable to the happiness of others.

It is obviously not within the scope of this paper to undertake even an adequate outline of the most acceptable and efficacious methods of handling the various forms of human behavior which might fall within the classification of the psychoneuroses. Some of the fundamental principles of such an approach have only been implied. No effort was made to discuss the undoubted influence of social and economic factors which now play such an important role in the production of anxiety states. These, however, affect such large groups of people in any given community that much of their anxiety may be regarded as falling within normal limitations of reaction to difficult situations which are not peculiar to any particular individual. There is little, if any, repression of such anxiety and, therefore, less typical psychoneurotic behavior than might be anticipated. I did, however, call attention to some of the conditioning influences of childhood and referred to compensatory neurotic reactions which are sometimes of value to the adult and which may be regarded as benign and inevitable formations of escape from the inner tension of threatening or unbearable states of emotional conflict.

Throughout this discussion I have endeavored to emphasize the tremendous constructive influence of the mental hygiene movement, and especially that of the National Committee in its various fields of activity. However, our principal interest has been stimulated by the increasing recognition, by psychiatrists and other mental hygienists, of the need of a better and more widespread understanding, by physicians generally, of the nature and what appear to be some of the sources of origin of the psychoneuroses. Since they are looked on as benign types of deviation in personality reaction, which are believed to have their origin in early childhood and to be dependent on various fixations at that period of life, they offer much encouragement to those who have sufficient knowledge, experience and patience to undertake a study of the total personality makeup and to investigate the motivations of its various types of behavior. The most frequent motivation in the average case presenting symptoms of psychoneurotic reaction to repressed anxiety is an evident tendency to regress to childlike or infantile types of behavior, representing various forms of escape from reality, and some of these by conversion may simulate serious somatic disease. Hence the need again of a thorough physical examination in any case presenting even the most clearly defined clinical symptoms of a psychoneurosis. This is not only of value in itself but will also increase the confidence of the patient and help to preserve his self esteem.

The regressive tendency in all the psychoneuroses is of such importance that it has justified the synonymous designation of "regression neuroses" for these disorders. It represents a reaction of dependence and lack of self reliance in times of stress and is evidence of more easy adaptability on a level of emotional immaturity. In other words it is an indication, at least in some degree, of inadequate character formation. This at once suggests the importance of character building

agencies during the formative period of childhood, including the home, the school, the church, the playground and other recreational facilities, along with the development of special skills and cultural outlets. All are valuable aids in the enhancement of a feeling of self reliance, an indispensable need of later life and one that will enable the individual to make emotional adjustments on a more mature level of adaptability. After a sufficient degree of insight has been given by whatever method may be employed, this is the goal which is sought in the treatment of adult psychoneuroses with regressive tendencies, many of which occur in persons who show unmistakable evidences of inadequate character formation in early childhood.

In efforts such as these, and others of equal importance, the mental hygiene movement has taken a prominent part, especially in recent years. It has supported the leadership of those who have demonstrated that much can be done in a program looking toward a better understanding of the mental health of people who give evidence of benign deviations of personality reaction and who constitute a considerable proportion of our most valuable population.

THE PHYSIOLOGY OF VITAMIN C

C. G. KING, Ph.D.

PITTSBURGH

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

ORIGIN AND PHYSIOLOGIC CONTROL

Dry seeds contain practically no ascorbic or dehydroascorbic acid but, when they are moistened and warmed, ascorbic acid appears within a few hours in the areas where the sprouting processes are apparently initiated.¹ Unripe, rapidly growing seeds, such as green peas, are relatively rich sources of the vitamin, but as ripening advances the concentration approaches zero. An extensive literature² indicates that all actively growing parts of the higher plants (roots, stems, buds and pods), all fresh green leaves, many of the algae³ and perhaps even bacteria⁴ contain significant quantities of the vitamin. The carotenoid pigments are frequently accompanied by high concentrations of ascorbic acid in both plant and animal tissues, as in rose hips, paprikas and corpora lutea, but there are many exceptions to such a relationship, as in vitamin rich, nonpigmented sprouts.

Of the extensive number of animals studied, only man, the other primates and guinea pigs do not have a

capacity to synthesize ascorbic acid. There is no convincing evidence that infants, placental tissue or any of the tissues of the animals named can synthesize ascorbic acid at any stage in their development. The evidence that is frequently cited in the literature to prove such a synthesis can be interpreted as well, and in most cases better, on the basis of selective conservation of the vitamin in the more vital tissues, such as the pituitary body, during a period of general body depletion. Furthermore, it is known that both human beings and guinea pigs are subject to scurvy during gestation and lactation. The early synthesis of vitamin C in chick embryos⁵ demonstrates a tissue reaction that is retained by the adult organism.

The claim that mannose could serve as a precursor of vitamin C in rat tissue could not be confirmed.⁶ There is still no clear evidence concerning the nature of the substance from which vitamin C is synthesized in animals or plants, nor is there any indication of the specific agencies or tissues responsible for the synthesis. The known metabolites in plants and animals that are most closely related to the vitamin are glucuronic and galacturonic acids. Either of these could give rise to the vitamin by replacement of the carbonyl group from the first to the fourth or fifth carbon, followed by lactonization and enolization.

The distribution of vitamin C in the human body⁷ is comparable with that in the guinea pig and in animals that synthesize a continuous supply in their own tissues, such as the rat and the chicken.⁸ Giroud⁹ has studied an extensive number of invertebrates. In general, the tissues that are characterized by a high metabolic activity have a high vitamin C content. Thus the individual tissues of young animals are consistently richer in vitamin C than those of older animals, and in special cases in which one can follow the changing vitamin content during cycles of activity and atrophy the relationship to functional activity is striking. An excellent illustration of this principle is provided by the microtitration studies of Glick and Biskind on thymus¹⁰ and corpus luteum.¹¹

Normal tissues from different animals do not fall in exactly the same sequence with regard to concentration, but the following order corresponds approximately to a general decreasing concentration of vitamin C: pituitary body (2.6 mg. per gram in the pars intermedia), corpus luteum, adrenal cortex, young thymus, liver, brain, testes, ovaries, spleen, thyroid, pancreas, salivary glands, lung, kidney, intestinal wall, heart, muscle, spinal fluid and blood. Normally the average content of human blood plasma is about 1.2 mg. of vitamin per hundred cubic centimeters,¹² but depletion reduces this to about

0.8 mg. as the "prescurvitic state" is reached and to approximately 0.5 mg. with the appearance of "clinical scurvy." Tumor tissue varies greatly with different types but generally shows a high content during rapid growth and a characteristic decrease with necrosis.¹³

In relation to infant nutrition and from the point of view of comparative physiology, it is both interesting and important to note that human milk normally contains from four to five times more vitamin C than cow's milk. The human infant has a high dietary requirement to meet the need for rapid growth and general metabolism, but the calf is not dependent on a dietary supply, its current requirement being met by tissue synthesis, as in the rat and the chick. When the human mother's diet is seriously deficient in antiscorbutic foods, however, the concentration in the milk gradually falls to approximately that of cow's milk,¹⁴ and when the vitamin C intake is increased, the antiscorbutic value of the milk returns to normal.

METABOLISM

Harris and Ray¹⁵ and later many other writers have shown that there is a continuous but decreasing urinary excretion of vitamin C when there is no dietary intake. When the body has become depleted of its normal vitamin C content, readministration of the vitamin first causes a restorage in the various tissues, and when the deficiency has been made up, urinary excretion of the excess again follows. Such balance experiments provide a reasonably satisfactory means of clinically evaluating the various stages of malnutrition. The net loss, or difference between intake and excretion, for a person in a state of "saturation" may be taken as an approximation of the quantity normally destroyed, or "burned," in the body daily. This value apparently varies considerably with different persons but may be estimated to fall in the range of from 25 to 50 mg. daily. It appears from the work of Hawley and her associates¹⁶ that the quantity of vitamin excreted may be varied by merely changing the acid-base balance of the food intake.

GENERAL PHYSIOLOGIC RELATIONSHIPS

The most clearly established functional role of vitamin C in animal tissues is its relationship to the physical state of the "intercellular material," as described by Wolbach and his associates. A detailed discussion of this field of study will be found in the section on pathology. The relationship of vitamin C to calcium metabolism is intimately associated with this phenomenon and is discussed in the same section. Both roles are clearly of major importance in relation to growth and repair of bones and teeth, and it is evident that other tissues, such as cartilage and white fibrous tissue, are markedly affected in a similar manner. The chemical mechanism through which the vitamin brings about this control of metabolism is still unknown.

From the close relationship between growth and vitamin C content it is reasonable to conclude that the vitamin has an essential role in the over-all growth processes of animals and plants. Work by Bonner and Axtman indicates that ascorbic acid serves as a powerful growth stimulant for young plant embryos that have been isolated from their seed reserve food supply.

Using the acid and silver nitrate staining technic, Bourne and Allen⁴ and Giroud and Leblond¹⁷ made detailed studies of the distribution of ascorbic acid within the cell, as well as the relative distribution in whole tissues. In an extensive series of papers from the two laboratories they have emphasized the association of the vitamin with the Golgi apparatus and mitochondria. Their results have served to emphasize the selective retention of the vitamin in certain parts of the cell and in vital tissues such as the pituitary body.

The anemia that accompanies depletion of vitamin C is thought to be due primarily to dysfunction of the tissues that form the red blood cells rather than to excessive destruction of cells or specific failure in synthesis of hemoglobin. The decrease in hemoglobin is roughly parallel to the decrease in red blood cells and is accompanied by a moderate decrease in clotting time and in the number of blood platelets.

When guinea pigs are given diets free from vitamin C or low intakes, impairment of physiologic functions can be demonstrated before growth is severely restricted or external evidences of scurvy appear. This "prescurbutic state" is clearly of common occurrence in the general population and in relation to human physiology and public health apparently represents an important field of investigation. Animals in such a border stage of deficiency are more sensitive to injury from injections of diphtheria toxin,¹⁸ and their normal metabolic activity, as measured by dextrose tolerance, is moderately lowered.¹⁹ Many, if not all, of the reports indicating detoxification by ascorbic acid in vitro apparently were due to underestimating the importance of pH effects.¹⁹ The arteries, teeth and adrenals are particularly sensitive to injury by toxins when the tissues are depleted of their normal vitamin C reserves. Resistance against infections is also lowered in the prescurbutic condition,²⁰ and it is worthy of note that bacterial toxins can cause losses of from 50 to 85 per cent of the vitamin normally contained in the adrenals.²¹

The claim by Szent-Györgyi that a new factor called "vitamin P" is responsible for the antihemorrhagic effect attributed to vitamin C has been shown to be erroneous. The postulated "vitamin P" apparently does not exist.²²

SPECIFIC RELATIONSHIPS TO ENZYMES

At the present time it is impossible to indicate with certainty any specific relationships between vitamin C and the enzymes in animal tissues so far as normal physiologic processes are concerned; but many papers

record activating and inhibiting effects on enzymes in vitro and it is not unlikely that some of the observed effects² will prove to be physiologically significant.

Both ascorbic acid and dehydroascorbic acid, and a number of their cation complexes (e. g., with Fe^{++} , Cu^{++} and Mn^{++}), have been reported to exert marked effects on specific enzymes, and studies on cathepsin, papain,²³ amylase,²⁴ arginase, catalase, urease,²⁵ tyrosinase and nuclease²⁶ have offered special promise. It is likely that many (but probably not all) of the observed effects are more or less fortuitous observations in vitro, with little bearing on the role of the vitamin in vivo. The results from different laboratories have not been in good agreement, and it is evident in some cases that the nonspecific acidity and reducing effects of the vitamin have caused changes that were attributed specifically to the vitamin.

The catalyst frequently called "ascorbic acid oxidase," which occurs widely in plant tissues, has been shown to have the composition and properties of a protein combined with copper, in which the copper serves as the active catalyst.²⁷ Since there is evidence that the catalyst, or enzyme, is not specific for vitamin C as a substrate,^{27a} the name should be discontinued.

The cytochrome-indophenol oxidase system has been shown to act as a catalyst for the aerobic oxidation of ascorbic acid, and there is evidence that this system is chiefly responsible for the observed (slow) aerobic oxidation of the vitamin in excised animal tissues.²⁸ In view of Barron's²⁹ work, the hemochromogens are also of interest.

Although the theory is widely held that vitamin C serves primarily as a hydrogen-transport agent, or respiratory catalyst, there is no clear-cut evidence to support the theory in relation to animal tissues.³⁰ The experiments of Hopkins and Morgan³¹ and of Borsook and his co-workers³² strongly support the theory in relation to plants, however, and place special emphasis on the role of glutathione in such a cycle in animal tissues.²⁸ A strong point against the theory that vitamin C functions as a major respiratory catalyst is the fact that depleted tissues do not show a decreased respiration capacity, and when ascorbate is added to the depleted tissues there is no rise in the true oxygen consumption. The livers of scorbutic animals show an increased oxygen consumption which is comparable to that shown by the entire body.³⁰

Recently Green and Richter³³ reported that ascorbic acid acts as an inhibitor in the adrenalin-adrenochrome

oxidation system in heart tissue. Lemberg, Cortis-Jones and Norrie³⁴ have studied a coupled type of oxidation of ascorbic acid and hemochromogens, extending the earlier work of Barron²⁹ and Karrer, especially correlating the coupled oxidation with verdohemochromogen formation from hematin.

Great interest is attached to the finding by Ecker and associates of a close relationship between vitamin C and guinea pig blood complement.³⁵ The reversible oxidation-reduction behavior of complement, as a single protein substance, was found to be dependent in large part on the ascorbic acid content of the plasma. The normal activity of complement was contingent on its being present in the reduced state. Although other reducing agents such as glutathione, cysteine and hydrogen sulfide could bring about the reduction and activation, ascorbic acid was found to be the reducing agent of major importance in vivo.

Reedman and McHenry³⁶ have reported an extensive study of the degree of conjugation of ascorbic acid with protein in plants, but there has been no evidence that compounds of comparable stability occur in animal tissues.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

CELLU BRAND APPLE RINGS

Distributor.—Chicago Dietetic Supply House, Inc., Chicago.

Description.—Slices of apples, peeled and without cores, packed in undiluted juice without added sugar.

Manufacture.—Roman Beauty apples are sorted, washed, peeled, cored, cut into rings or slices and blanched. The slices or rings are placed in cans, covered with undiluted apple juice, vacuum sealed and heat processed. The spray residue on the apples used is kept within the federal tolerance.

Analysis (submitted by manufacturer).—Moisture 87.4%, total solids 12.6%, ash 0.2%, fat (ether extract) 0.3%, protein ($N \times 6.25$) 0.1%, reducing sugar as invert 6.7%, sucrose (by copper reduction) 2.7%, crude fiber 1.0%, carbohydrates other than crude fiber (by difference) 11.0%.

Calories.—0.47 per gram; 13 per ounce.

- (1) BURTON'S PURE LEMON EXTRACT
- (2) BURTON'S PURE ALMOND EXTRACT

Manufacturer.—W. Burton & Company, Inc., a wholly owned subsidiary of Fred Fear & Co., Brooklyn.

Description.—(1) Lemon extract containing ethyl alcohol, lemon oil and water.

(2) Almond extract containing water, ethyl alcohol and pure oil of almond.

Manufacture.—(1) The lemon oil is dissolved in ethyl alcohol, water is added and the mixture is filtered and bottled.

(2) The oil of almond is dissolved in ethyl alcohol, water is added and the mixture is filtered and bottled.

Analyses (submitted by manufacturer).—(1) Alcohol, by volume, 90%; water, by volume, 5%; oil of lemon, by volume, 5%. (2) Alcohol, by volume, 20%; water, by volume, 78.09%; oil of almond, by volume, 1.01%.

NUTRADIET BRAND APPLE SAUCE

Distributor.—The Nutradiet Company, a subsidiary of S & W Fine Foods, Inc., San Francisco.

Description.—Cooked strained apple sauce, packed without addition of sugar.

Manufacture.—Properly matured apples are graded, inspected, passed through water sprays to remove spray residues, and peeled. The peeled apples are washed, inspected, cut, steamed for seven minutes, strained and automatically packed into cans, which are sealed and processed.

Analysis (submitted by manufacturer).—Moisture 87.1%, total solids 12.9%, ash 0.2%, fat (ether extract) 0.04%, protein ($N \times 6.25$) 0.2%, crude fiber 0.5%, carbohydrates other than crude fiber (by difference) 11.46%, titratable acidity as malic acid 0.5%.

Calories.—0.47 per gram; 13 per ounce.

Claims of Manufacturer.—For diets in which sweetened fruit is proscribed.

MRS. PALEY'S BABY FOOD—STRAINED VEGETABLE SOUP WITH BEEF BROTH AND CEREAL

Manufacturer.—Paley-Sachs Food Company, Houston, Texas.

Description.—Strained vegetable soup containing beef stock, carrots, potatoes, tomato purée, soya beans, onions, cabbage, celery, barley and brown rice, slightly seasoned with salt.

Manufacture.—U. S. government inspected beef is wiped with a damp cloth and cut into small pieces. Meat and water are allowed to stand in a cool place for four hours, heated slowly and cooked. The juice is pressed out of the meat and cooled, the fat removed, and the stock cooked with the vegetables which have been cleaned and cut into pieces. The barley, brown rice and soya beans are soaked, precooked, and added to the stock and vegetables, and cooked in air-tight pressure cookers. The mixture is then strained, filled, sealed in vacuum sealing machine and heat processed.

Analysis (submitted by manufacturer).—Moisture 84.2%, total solids 15.8%, ash 1.1%, fat (ether extract) 0.2%, protein ($N \times 6.25$) 2.6%, reducing sugars as dextrose 1.3%, sucrose 0.96%, crude fiber 1.02%, total carbohydrates other than crude fiber (by difference) 10.9%, calcium (Ca) 0.016%, phosphorus (P) 0.071%, iron (Fe) 0.001%.

Calories.—0.6 per gram; 17 per ounce.

ASTORIA BRAND FREE-FROM- PRESERVATIVE CHERRIES

Manufacturer.—Fruit Products Corporation, Belleville, N. J.

Description.—Bottled, sweetened cherries free from preservatives; oil of bitter almonds, citric acid, U. S. Department of Agriculture certified color and a small amount of alcohol are added. The alcohol is used to dissolve the flavoring.

Manufacture.—Royal Anne Cherries, No. 1 grade, are immersed in a dilute solution of hydrochloric acid to remove spray residue, washed, placed in a solution of sulfurous acid (3,000 parts per million of SO_2 in water) to bleach the cherries, destroy any organic living matter and preserve the fruit until it is heated. The cherries are washed several times, pitted and stemmed by hand, blanched, again washed in cold water and colored in cold water with U. S. Department of Agriculture certified color. The fruit is heated in sugar syrup containing a small amount of citric acid and allowed to stand in the syrup until the fruit and juice cool to room temperature. The fruit is drained and packed in bottles. Fresh syrup containing citric acid, oil of bitter almond flavoring and a small amount of alcohol is added and the bottles are automatically sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 70.0%, total solids 30.0%, ash 0.2%, fat (ether extract) 0.2%, protein ($N \times 6.25$) 0.2%, reducing sugars as invert sugar 5.6%, sucrose 22.8%, crude fiber 0.3%, carbohydrates other than crude fiber (by difference) 29.1%, sulfur dioxide none, sodium benzoate none, certified food color present, flavor present.

Calories.—1.2 per gram; 34 per ounce.

THE PROBLEM OF THE REFUGEE PHYSICIAN

The anti-Jewish campaign of the German government, reflected in the Berlin letter in this issue of THE JOURNAL, and the more recent actions taken in Austria and in Italy have brought prominently before the American medical profession the problem of the physician who is a refugee. Important is a knowledge of the scope of the problem, for which exact data are required. Table 1, secured through the assistance of the Immigration and Naturalization office of the United States Department of Labor, gives the number of immigrant alien physicians from Austria, Germany and Italy during each of the years from 1928 through 1938.

TABLE 1.—Immigrant Aliens from Austria, Germany and Italy (Last Permanent Residence) Admitted to the United States as Immigrant Aliens for Permanent Residence, Whose Profession or Calling was Physician, Years Ended June 30, 1928 to 1938

During	Immigrant Physicians from:		
	Austria	Germany	Italy
1928.....	3	22	11
1929.....	5	22	11

1937.....	15	271	14
1938*.....	62	302	26
Totals.....	149	1,144	139

* Figures for the last fiscal year subject to possible slight change when final statistics for that year become complete.

With the aid of the state medical licensing boards and the Council on Medical Education and Hospitals, table 2 was prepared of the graduates of foreign schools licensed in the United States in the years 1928-1937 inclusive.

While the total number of physicians coming to this country from abroad may not be great, the problem is

increasing. No doubt the difficulty may well continue until all living Jewish physicians from Germany, Austria and Italy have been transplanted. Perhaps six to seven thousand physicians will be absorbed by the rest of the world, approximately 3,000 being already absorbed.

Interesting observations develop from a comparison of the two tables here included. Apparently many American citizens are studying abroad, securing diplomas from foreign medical schools and returning to the United States. Thus 271 immigrant physicians came from Germany in 1937, but 335 were licensed, making some sixty Americans who returned. Fifteen immigrant aliens came from Austria in 1937, but the total number licensed was eighty-four, making sixty-nine who were probably American citizens. One hundred and thirteen immigrants from Italy were licensed in 1937, but only fourteen were aliens. The American

TABLE 2.—Graduates of Foreign Schools Licensed in the Years 1928-1937 Inclusive

Medical Association has called attention repeatedly for the last ten years to the problem of American physicians studying abroad in schools of lesser rank than those available in this country and then returning to the United States to secure licensure.

This problem is one which is already concerning the various state medical licensing boards, since the licensure of doctors to practice is still within the power of the individual states. The question of restriction of immigration is one which will no doubt come before the Congress of the United States. The situation is fraught with difficulties arising from economic stress, chauvinistic prejudices, fears that have been stimulated by propaganda, and other motivations. The American Medical Association through its House of Delegates at the San Francisco session adopted a resolution expressing the desirability that foreigners, graduates of foreign institutions, be required to obtain full citizenship in the United States before being admitted to practice. It is significant, as reported by the correspondent from Warsaw in this issue (page 1120), that hasty action has resulted in a disruption of the national medical association of Poland, leaving the physicians as a profession at the mercy of the politicians. Only by careful sympathetic consideration will a reasonable solution be possible.

CHANGING POPULATION: THE PREMISE

The probable future population of this and other countries is, as has been pointed out editorially in *THE JOURNAL*,¹ important for long-range planning in health matters as well as in other economic subjects. Recognition has been accorded this fact by the federal government in a lengthy report to the National Resources Committee on the problems of a changing population.² According to the estimates of Warren S. Thompson and P. K. Whelpton, based on medium fertility and mortality rates, the population in the United States will continue to grow for fifty years but at a constantly decreasing rate, reaching 152,000,000 in 1980. Even with the highest rate that might reasonably be assumed, there would be a natural increase of less than 50,000,000 from 1935 to 1980. The minimum estimate on the other extreme would give a peak population of 138,000,000 in 1955 with a decrease of 10,000,000 during the succeeding quarter century.

These alternate estimates are based on extension of trends of birth rates and death rates now in evidence with allowance for certain qualifying factors. They all assume, however, that the span of life cannot be greatly extended—at least in comparison with the results of the past—and that there will be no sudden or complete reversal in the birth rate or any extraordinary effect on the size of the population from immigration or emigration.

These assumptions are an integral part of the forecast and the conclusions which the latter imply. The earliest life table for any area or population of the United States was that of Wigglesworth for Massachusetts and New Hampshire for the year 1789. According to his computation the expectation of life at birth at that time was 34.5 years for males and 36.5 years for females. While these results cannot perhaps be accepted at face value, the life expectancy for the total population of Massachusetts was 43.5 years in 1890. This may be compared with the expectation for the white population of the United States in 1929-1930 of 59.3 years for males and 62.6 for females. The improvement, while striking, may be compared, the report states, with the still longer expectation obtaining in New Zealand in 1931 of 65 years for males and 68 years for females, or in South Dakota in 1930 of 64.4 years for males and 66.8 years for females. These varying figures on life span indicate that the immediate prospects of attaining a great increase in life expectancy beyond present figures are not good.

The assumption that the birth rates will continue their present trend is difficult either to affirm or to deny. It is probable, but of course accurate evidence is lacking, that there has never been a time in man's past when the number of children born in proportion

to the number of women in the childbearing ages has been less. The biologic significance of this phenomenon is obscure. Likewise it cannot be said with certainty as yet that this apparent trend toward reversal of fertility is permanent. It is of too recent origin biologically, if not statistically, to constitute a thoroughly acceptable concept. If it is not to be continued, then the whole fabric of prophecy will collapse. It is most unfortunate in this connection that Clyde V. Kiser's discussion of the role of contraception on differential birth rates should have been deleted from the report.³ If this factor is as important as is generally believed, its present and future influence on birth rates must be profound.

The report allows for a moderate amount of immigration after 1940 in some of the alternate estimates. This factor is at present an imponderable: the degree to which immigration may or may not occur is intimately bound up with mass psychology and the economic and labor pictures. Neither society as a whole nor governments individually have yet succeeded in consciously influencing any of these factors with conspicuous success. The effect of possible emigration on the population apparently has been ignored in the report. While there is certainly no reason to expect it in any ponderable quantity, it is a factor which might occur and should at least be mentioned.

Although this report on population may be considered one of the best that has ever appeared on the subject, its prophetic validity rests on certain assumptions the correctness of which only time can prove.

THE TYRANNY OF ABBREVIATIONS

When abbreviations are used in medical papers, in the recording of case histories or physical examinations or in operative or pathologic reports, the meaning should be entirely clear to all who may have occasion to read them. This is not, of course, the case. Abbreviations of medical terms are used obviously to save the time of the writer; too often, however, the time thus saved is wasted many times over by the person who is trying to decipher the meaning originally intended. When placed within a context, many of the abbreviations commonly employed in medicine are reasonably clear to those intimately familiar with the particular field; but when removed from such environment they become even more abstruse. Few readers for example can probably identify with ease such fairly commonly employed abbreviations as M. T. R., PcB, P. P. D., M. E. D., s. e. d., M. K. R. or K. P. Even when the abbreviations are placed in the proper setting many medical men would have difficulty in translating PcB into "near point of convergence," M. T. R. into "Meinicke flocculation reaction" or M. E. D. into "minimal erythema dose."

2. The Problems of a Changing Population, Report of the Committee on Population Problems to the National Resources Committee, May 1938.

3. Notestein, Frank W.: Population Index 4:136 (July) 1933.

Although for the uninitiated the ophthalmologists possess probably the worst collection of uninterpretable abbreviations, such as K. P. for "keratitis punctata," Hm for "hyperopia manifest," O. U. for "oculus uterque (both eyes)," M. A. for "meter angle" and so on almost ad infinitum, those in other fields are by no means free of criticism. The average physician would usually interpret P. S. P. as the "phenolsulfonphthalein test," M. L. D. as "minimal lethal dose" and possibly P. P. D. as "purified protein derivative," but others who also may need to translate such initials, including manuscript editors, social service workers and statisticians, may have serious difficulties. Sometimes the attempt at interpretation gives rise to persistent errors of more or less serious nature, such as the reasonable interpretation of *E. coli* as "*Endamoeba coli*" when it should have been "*Escherichia coli*."

Hours sometimes have been spent in attempting to decode the meaning of such abbreviations. The use of such short cuts to expression may be an indication of unnecessary haste, careless recording of notes, or slipshod methods of experimentation and study. Reports are written for the reader, not the author, and the reader should not have to be an expert in cryptography to find out what it is all about.

Current Comment

THE UNCARED-FOR MILLIONS

The Statistical Bulletin of the Metropolitan Life Insurance Company, basing its figures on reports from millions of industrial policyholders, is regarded as a prompt and reliable indicator of trends in public health, morbidity and mortality. Census Bureau final figures are necessarily delayed. Even the provisional death rates published annually by the United States Public Health Service are not available until some months have elapsed. The current figures published in the life insurance company's bulletin, therefore, afford interesting indications. Over a period of years they are found to parallel closely the final figures published later. Just now it is popular in certain circles to refer to the millions of Americans who are unable to procure medical care because of inability to pay for it. The low income groups, it is said, fare worse than the frankly indigent, because the latter get for nothing what the former are unable to buy and are too proud to accept on any other basis. What then are actually the health and mortality trends in the low income groups—the people who buy weekly payment industrial insurance? According to the Statistical Bulletin:¹

We live in an age of records. Some are justly proclaimed with banners flying and sirens screeching. Others, and not the least important, are achieved quietly, without the blare of trumpets, and would, indeed, pass altogether unnoticed were it not for statistics and statisticians. Their "dry" figures tell us that we are living in a period of remarkable achievements in public welfare. Our death rate, after a series of

continued lows, has, in the first six months of the current year, bettered last year's figure by no less than 10 per cent and has thereby established an all-time record that may justly be described as phenomenal.

In a succeeding paragraph we find:

With each succeeding month the mortality record for this year becomes more and more favorable. . . . Encouraging reports about the death rate in the general population of the United States come from various sections of the country. Alabama, Connecticut, Illinois, Indiana, Maine, Maryland, Michigan, Minnesota, New York, South Dakota and Virginia all report drops—and, in most instances, decided drops—in the number of deaths this year as compared with last.

Most significant of all is this statement, the italics being in the original:

. . . to date, it is apparent that *depression and widespread unemployment have done no visible harm to public health.*

PSYCHIATRIC ASPECTS OF ARTIFICIAL FEVER THERAPY

In treating approximately 400 patients with the Kettering hypertherm, Ebaugh and his colleagues¹ noted that fever therapy appears to exaggerate a subject's main personality characteristics. The phlegmatic patient was generally little perturbed by the rise in temperature and was generally cooperative; the aggressive person commonly manifested signs of aggression and restlessness; the contented, sociable person became elated and even euphoric during hyperpyrexia. Exaggeration of personality patterns during the fever therapy was so consistent that, these authors believe, one might reasonably predict the individual patient's reaction to pyretotherapy if a previous evaluation of personality had been made. A common problem encountered in a department of fever therapy is the anxious, unstable person who is greatly concerned about his physical self and is apprehensive concerning fever therapy. He is peculiarly predisposed to delirious episodes and is often better rejected for hyperpyrexia, at least before suitable psychotherapeutic measures. The most important psychiatric problem of the fever therapist is the management of delirious episodes associated with hyperpyrexia. The number of such reactions, however, has been reduced in the later experience of these investigators. This is attributed to the application of psychotherapeutic measures, increased experience with fever therapy and careful control and avoidance of sedatives except when necessary. During the past year in the limited number of treatments in which sedatives were required, one dose of pentobarbital sodium 0.1 Gm. (1½ grains) or morphine sulfate 0.01 Gm. (one-sixth grain) was prescribed. Codeine sulfate 0.03 Gm. (one-half grain) was the drug of choice when sedation was necessary for children. Of the 350 patients who had delirious episodes during hyperpyrexia therapy, 200 were observed from February 1935 to February 1936, the incidence being one episode of delirium in four treatments. In the second series of 150 patients, observed from February 1936 to February 1937, the incidence dropped to one episode of delirium in eighteen treatments.

ORGANIZATION SECTION

WHERE ARE HOSPITALS MOST NEEDED?

In determining whether and where there is need of additional hospital facilities, it is obviously necessary first to ascertain the extent to which existing facilities are being utilized. In the accompanying table the states are arranged in the order of the number of their general hospital beds per thousand of population. Mississippi, having the least hospital facilities, has 1.4 beds per thousand. At the other end of the scale, the District of Columbia has 8.6 beds per thousand, many of which, however, serve not the inhabitants of the district only but federal employees throughout the country.

Dividing the states into groups having hospital facilities in the ratio of 1:2, 2:3, 3:4, and so on beds per thousand, the utilization of these facilities in each group steadily rises as the number of hospital beds increases. Six states with from 1 to 2 beds per thousand show a use of 60.45 per cent. The next group, ten states, with hospital beds running from 2 to 3 per thousand, report 64.61 per cent occupancy. The next group, seventeen states with a ratio of from 3 to 4 beds per thousand, keep these beds 67.67 per cent filled. In eleven states, with from 4 to 5 beds per thousand, utilization is 69.96 per cent. In four states having from 5 to 6 beds per thousand, occupancy drops to 62.68 per cent.

It is obvious, therefore, that hospital facilities are most used where they are most abundant and that where the ratio of beds to population is lowest the rate of occupancy is also lowest. In other words, hospitals have been built in response to a community demand and have not, as a rule, been built where there is no demand. Doubtless some states would show a higher rate of occupancy if additional funds were available for hospitalization of the indigent. In other states, education is needed to overcome popular prejudice. In any case, no single formula for hospital facilities is applicable to all parts of the country or to the habits and customs of all the people.

WEST VIRGINIA'S ADULT PHYSICAL REHABILITATION PROGRAM

In West Virginia 923 men, who a comparatively short time ago were listed on public relief rolls as "unemployables" because they were suffering from minor physical ailments of one sort or other, now occupy places in private industry throughout the state. An additional 581 men, physically rehabilitated and no longer listed as unemployables, were awaiting placement, and 245 were convalescing in hospitals.

The economic outlook for these men was, every one agreed, doubly bleak. Not only had they been caught in the backwash of a worldwide depression, but the doors of private industry were closed to them because of their physical disabilities. Relief officials had accepted them as permanent charges.

Today, as a result of an experiment in human rehabilitation conducted by the West Virginia Department of Public Assistance in cooperation with the state medical society, a large percentage of these men have been restored to gainful employment.

The average cost to rehabilitate and restore to private industry each of these men has been \$94.35. The average cost to maintain a person on the state's relief rolls for one year is \$226.87.

Thus taking into consideration only these 923 men who have already resumed gainful employment, the state will, at the end of their second year of employment, realize a 100 per cent savings on its original investment, or \$209,401, the amount which would have been required to keep them on relief rolls. This figure does not take into consideration reimbursements for hospitalization, artificial limbs and other expenses which the recipients are expected to make to the state, or the fact that as additional men are absorbed by private industry the annual saving will be increased.

This is the economic side of the picture. Aside from the commercial aspects of the program, the vastly more important social aspects are apparent—new hope for the future, independence for individuals and their families; the effects are far reaching and incalculable.

In 1934 Charles Ritter, director of compensation for the West Virginia Relief Administration, set about interesting relief officials in physical rehabilitation. He succeeded in obtaining \$1,000 for the purpose of rehabilitating a small group of handicapped persons who would otherwise remain on relief rolls. The

experiment worked so convincingly that \$20,000 was earmarked for this work the following fall. Ritter was advised and assisted by a committee of physicians. Joe Savage, secretary of the West Virginia Medical Association, helped him work out details of the plan.

When the public welfare law creating the new state department of public assistance was passed in June 1936, the rehabilitation work was made a part of the law and the division of adult physical rehabilitation, with Mr. Ritter as supervisor, was set up in the new department.

A report issued as of April 30, 1938, shows that, of 1,951 persons referred to the division, 1,565 have been rehabilitated and are able to resume gainful employment, 245 are convalescing in hospitals and 141 refused to accept hospitalization. Of the 1,951 persons, sufferers from hernia led in number with 507. Second in numerical importance, 365, were victims of impaired vision. Those requiring artificial limbs or other aids for physical handicaps numbered 166. Fractures of various kinds were involved in 136 cases. Other handicap causes included (with the number of cases in each category) renal and rectal disorders 123, hemorrhoids sixty-one, cataracts sixty-eight, goiter eighty, gallstones forty-six, tumors forty-nine, varicose veins forty-six, salpingitis thirty-seven, kidney stones thirty-one, ulcers thirty-six, osteomyelitis twenty-four, trachoma twenty-three, nervous disorders twenty, appendicitis fourteen, fistula nineteen, mastoids eighteen, ankylolysis twenty-one, paralysis twenty-one, abscessed lungs sixteen, prostate gland nine.

Total relief grants for these 1,951 cases, less 103 incurables, was \$419,253. The total cost of rehabilitation has been \$177,233, or 42 per cent. Thus the savings to the state above the cost of rehabilitation represents \$242,019, or 58 per cent. A more detailed tabulation, by Supervisor Charles Ritter, is given in the accompanying table.

To be eligible for rehabilitation, applicants must be at least 18 years of age, citizens of the United States and on relief rolls. Since the program is primarily designed to restore handicapped persons to private industry, only those capable of being thus absorbed are accepted.

Details of Cost of Rehabilitation

General relief grants	
Public	
Estimate	
Administration expense	44,184.00
Total grants and cost of relief in 1,951 cases less 103 incurables, 1,848 cases	\$419,253.16
Total cost for adult physical rehabilitation operative cases	\$137,405.32
Total cost for artificial limbs and prosthetic appliances	27,045.00
Total administration expense	12,783.22
Total cost of adult physical rehabilitation—1,951 cases	\$177,233.54
Savings over cost of rehabilitation	\$242,019.62
General relief, public assistance, commodity grants and administrative expenses for 1,504 persons completely rehabilitated and able to resume gainful employment April 30, 1938, average cost per person, \$226.87	\$341,212.48
Total cost of physical rehabilitation in 1,504 cases, average cost per case \$94.35	141,902.40
Savings over cost of adult physical rehabilitation	\$199,310.08
General relief, public assistance, commodity grants and administrative expense for 923 persons who resumed gainful employment April 30, 1938, average \$226.87	\$209,401.01
Total cost for 1,504 persons completely rehabilitated, average cost \$94.35	141,902.40
Savings first year	\$ 67,498.61
Savings each succeeding year	209,401.01
Total savings end second year and each succeeding year on 923 persons returned to gainful employment April 30, 1938	\$276,899.62
Total number of persons returned to gainful employment April 30, 1938	923 or 61.4%
Total number of persons able to return but not yet returned to gainful employment April 30, 1938	581 or 38.6%
Total able to return to employment April 30, 1938	1,504 or 100%
Total persons approved to April 30, 1938	1,951
Total persons completely rehabilitated	1,565
Total persons convalescing and in hospitals, April 30, 1938	245
Total persons approved but refused hospitalization	141
Total	1,951

GRADUATE MEDICAL EDUCATION

A PROGRESS REPORT OF THE FIELD STUDY ON GRADUATE MEDICAL EDUCATION IN THE UNITED STATES
BEING CONDUCTED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

MASSACHUSETTS

The Committee on Postgraduate Medical Instruction of the Massachusetts Medical Society was organized in March 1933 with Dr. Frank R. Ober as chairman, Dr. Leroy E. Parkins as secretary and with an executive committee, of which Dr. Reginald Fitz is chairman. This group has remained essentially unchanged, the three physicians originally interested in postgraduate instruction still being members of the executive committee of five. On the committee on postgraduate instruction are representatives of all sections of the state society, the chairman of the standing committee of medical education and diplomas and public health, the editor of the *New England Journal of Medicine*, the state health commissioner, the state commissioner of mental disease, the deans of Boston University School of Medicine, Tufts College Medical School and Harvard Medical School, or their representatives, and the president of the Boston Medical Library. This group formulates plans and policies, organization and administrative details being left to the executive committee.

When this organization was perfected the Harvard Medical School abandoned its extension courses for physicians, since the Massachusetts Medical Society had recognized its duty to provide graduate instruction for the profession. From the start, the committee has had the active support of such groups as the state health department, the state department of mental disease and numerous community and private hospitals.¹

The first postgraduate program was given in September 1933 in twenty-four centers of the state, local hospitals being utilized. A faculty of 174 physicians was carefully selected on their merits as postgraduate teachers. Two hundred and forty two hour sessions were given the first year. Each instructor received expenses but not an honorarium. Teams of two or three members visited various district societies in the state giving a series of ten weekly comprehensive review demonstrations and lectures. Physicians in each district had an opportunity to choose subjects from a list of twenty-two topics submitted by the postgraduate committee.

A local chairman was appointed for each district. He was nominated by the executive committee and approved by the district society. This physician had charge of local registration, preparation of clinical material, attendance and other local details. The state society appropriated \$1,000 yearly for this postgraduate enterprise, and each physician who registered for the ten lecture series paid a \$5 fee. The secretary of the executive committee received compensation for his services and clerical assistance. The headquarters of the state medical society became the headquarters of the postgraduate committee.

One thousand and two of the 4,406 practicing physicians active in the state society registered for instruction during the first year. There are 7,263 licensed physicians in Massachusetts. The second year such subjects as cardiovascular disease, nutrition, endocrinology, obstetrics and gynecology, surgery and industrial medicine were selected from a list submitted by the postgraduate committee. It became apparent as the plan progressed that representatives of district societies evidenced a feeling that local programs might be set up by the districts.

¹ 1. Parkins, Leroy E.: The Relation of Postgraduate Medical Instruction to Public Health, J.A.M.A. 103:545 (Aug. 25) 1934.

themselves. It also seemed significant that instruction in certain subjects, such as venereal disease, was not chosen in spite of current propaganda regarding these diseases. The evaluation of instructors was recognized as a problem which required proper consideration.

In the fourth year in which the extension courses were given, reports of the committee on postgraduate instruction indicated that registration fees made up approximately 83 per cent of the revenue, that the remaining 17 per cent was made up by the state society's appropriation of \$1,000, and that at the end of that year, after all expenses had been paid, a credit balance remained.

The council of the state society voted in 1937 to suspend the activities of the postgraduate committee until it was determined what plans for continuing the education of physicians could be developed under the impetus of the Social Security Act. Since the United States Public Health Service and the Children's Bureau of the Department of Labor delegated the administration of postgraduate courses to the state department of health, the state commissioner of health, Dr. Henry D. Chadwick, requested the executive committee of the state society to assist in organizing a faculty and in directing a program of instruction in a manner similar to the programs of the preceding four years. It was arranged, therefore, to give a series of from eight to ten sessions in eighteen places throughout the state on a budget of approximately \$5,000. This allowed a \$25 honorarium plus travel expense for each instructor, providing for approximately 136 sessions. One thousand dollars was appropriated for the expense of administration. The plan was approved by the council of the state society and finally by the state federal agencies, thus providing opportunities for postgraduate instruction without charge for licensed physicians in Massachusetts, the state medical society underwriting the expenses of incidentals, printing of programs, clerical assistance and additional administrative aids. The original committee continued to function with these modified plans with the full cooperation of governmental agencies.

Of the subjects offered for discussion, it is interesting to note those chosen by district societies. Obstetric topics were requested approximately twice as often as the next subject, therapeutics, while instruction in pediatrics was third in demand. Lectures on pneumonia, scarlet fever, heart disease, rheumatic fever, syphilis and gonorrhea were each requested by about two thirds of the district societies. It is interesting to note also that, while instruction in tuberculosis was offered, none was requested. Fifty-six physicians now constitute the extension course faculty with five chairmen who are in charge of the various divisions of instruction. District societies are urged to present clinical cases whenever possible, all meetings being held in or near hospitals. Lantern slides, many in natural color, and teaching exhibits are being utilized in this extension course. Seven hundred and eight practicing physicians received training under the new plan during the past year, an increase of 35 per cent over the preceding year.

Harvard Medical School offers courses for graduates in such subjects as anatomy of the nose and throat, electrocardiography, fractures, minor surgery, medicine, obstetrics, orthopedic surgery and pediatrics. Each carries a fee, and attendance for each course is limited. Special postgraduate facilities have been set up also under a grant from the Commonwealth Fund of New York. These will be considered in a subsequent report.

The New England Medical Center, consisting of the Boston Dispensary, the Boston Floating Hospital and Tufts College Medical School, was established seven years ago with the aid of the Bingham Associates Fund. It provides opportunities for postgraduate instruction of New England physicians. Only physicians from Maine have been able thus far to take advantage of these opportunities.

Boston University School of Medicine cooperates actively with the state society in its extension course program. The dean, Dr. Alexander S. Begg, is secretary of the Massachusetts Medical Society. Members of the faculties of Boston's three approved medical schools comprise a major portion of the society's extension course faculty.

The Boston Medical Library has been the home of the Massachusetts Medical Society since 1879. The library is the depository for periodicals, reprints and books received by

the state society and by the *New England Journal of Medicine*. In company with other medical libraries of Boston, a cooperative plan to provide for nonduplication of reference and research material is being instituted. The annual library dues are \$15.

COLORADO

One standing committee and five special committees in the Colorado State Medical Society are concerned with medical education. Three of these, namely the committee on mid-winter postgraduate clinics, the Rocky Mountain medical conference and the committee on cancer education, have been especially active.

The Midwinter Postgraduate Clinics have been held in Denver for three days each January from 1933 until 1937, when a December meeting was held instead of a January 1938 session. All physicians in Colorado and adjoining states are invited. A registration fee of \$2 was charged last year. Clinics, symposiums, lectures, ward walks and clinical pathologic conferences characterized the graduate assemblies. Morning clinics were held in private hospitals or at the University of Colorado School of Medicine, with demonstrations by staff members. Afternoon and evening sessions took place in a downtown hotel, which was used as headquarters for the meeting. Local physicians, many of whom are members of the staff of the school of medicine, and five out of state speakers participated last year. Instructors are selected by the state society's committee, which is entirely responsible for the conduct of the meetings. Guest speakers are provided with travel and hotel expenses. This year Dr. G. M. Blickensderfer is chairman of the clinics' committee of five.

Subjects for discussion are chosen after questioning Colorado physicians as to their needs. Last year clinics on pediatrics, renal and prostatic disease, fractures, tumors and obscure fevers and a movie program devoted to neuropathology and neurosurgery featured the meetings. Three hundred and three physicians attended in December 1937, which was four times as many as registered in 1933. Of these, 102 came from outside Denver. In addition to physicians, sixty-two medical students and nurses registered at the December 1937 clinics. Registration represented forty-five cities and towns in Colorado and thirteen cities and towns in six other states.

The annual two day Spring Clinics of the Pueblo County Medical Society were started in 1934. They are held each April by the county medical society with the sponsorship of the Colorado State Medical Society. Each of four local hospitals has a representative on the clinic committee, with Dr. George A. Unfug as chairman. The local committee is assisted by the Committee on Postgraduate Clinics of the Colorado State Medical Society and selection of instructors is made jointly. Each hospital offers its facilities and provides a half day's program and each invites an out of state guest speaker. Local physicians show cases, give illustrative lectures and demonstrate procedures of value in practice. This year the differential diagnosis of pulmonary tuberculosis, the diagnosis and treatment of diaphragmatic hernia, hypothyroidism and symptoms and diagnosis in general medicine were the subjects of major interest. Programs are mailed to all physicians in Colorado and to others in the states of New Mexico, Kansas, Nebraska, Wyoming and Utah. The registration fee of \$2 provides admission to three luncheons, a banquet and a smoker. One hundred and sixty-three physicians registered last April, ninety-three coming from outside Pueblo. Twenty-eight enrolled from Denver, and twenty-eight cities and towns and five states were represented.

The Western Slope Clinical Meeting was inaugurated and conducted by the Mesa County Medical Society at Grand Junction in April 1938 for physicians practicing on the western slopes of the Rocky Mountains. It will be held annually hereafter. The day's program was opened by the executive secretary of the Colorado State Medical Society. Lectures on obstetrics, anesthesia, diagnosis of heart disease and peptic ulcer, including treatment, round table discussion on obstetrics, and five motion pictures on surgical procedures comprised the program. All physicians in western Colorado and eastern Utah

were invited. Fifty registered, twelve counties in Colorado and three in Utah being represented.

The Rocky Mountain Medical Conference was organized in 1936 at the suggestion of Dr. George P. Lingenfelter, chairman of a committee of four members from the Colorado State Medical Society. It is the purpose of this conference, which is a joint effort of the state societies of Colorado, New Mexico, Wyoming and Utah, to foster discussion of problems in medicine and public health which are peculiar to this region. The medical society in each state has approved of the conference as a means of obtaining prominent educators to address the physicians of these states, which are so sparsely settled. The Colorado society acted as host for the first three day meeting held in Denver in July 1937, but no Colorado physicians participated in the program. It is planned to have similar meetings every two years, the next being scheduled for Utah in 1939.

Twenty out of state speakers discussed such subjects as gastro-enteric disease, cranial nerve lesions, syphilis, cancer, fractures, hand injuries, urologic diseases and obesity in children, endocrinology, ophthalmology, Rocky Mountain spotted fever, parasitic and infectious disease, chemical warfare injuries, aviation and automobile trailer problems in medicine and national legislation affecting physicians. From three to five round table luncheons were held each day in three hotels with guest speakers leading the discussions. Attendance at each luncheon was limited to fifty physicians. Ten scientific exhibits supplemented the program's illustrated lectures. Technical exhibits were shown by twenty-five firms at the hotel headquarters. The Denver Chamber of Commerce assisted in registration, the fee being \$3. A local theater donated its auditorium for morning sessions to amplify the hotel facilities.

Seven hundred and eighty-seven physicians, 400 from Denver, registered for the conference. Twenty-five states and the District of Columbia were represented, six or more physicians coming from Wyoming, Utah, Texas, New Mexico, Kansas, Nebraska, and Illinois. Dr. Kenneth D. A. Allen was chairman of the conference executive committee, with representatives from the four cooperating states. Travel and hotel expenses, but not honorariums, were paid with funds derived from the commercial exhibits, donations from most of Colorado's county medical societies, special medical organizations and individuals. The city council of Denver and the Denver Convention and Tourist Bureau also contributed. Registration fees and the sale of luncheon and dinner tickets provided the remainder of the \$6,550 collected, which was more than sufficient to finance the effort.

The committee on cancer education of the state medical society was formed in 1932 to supply component medical societies with teams of from three to five physicians for training their members in the early recognition and treatment of cancer. Since 1935 every society has been addressed one or more times by a physician or surgeon, pathologist and radiologist on cancer of the cervix, breast and/or gastro-enteric tract. Eighteen of the twenty-eight component societies in the state were visited last year. Dr. Charles B. Kingry, acting chairman of the committee, with the aid of eight other members and special counsel, is preparing a handbook on the diagnosis and treatment of cancer for distribution to practicing physicians. An outline of examination procedures has been sent to members of the state society urging complete examinations in all suggestive cases.

The Medical Society of the City and County of Denver established a medical library in 1910 by effecting a merger with the Colorado Medical Library and the Denver Academy of Medicine Library. Sixteen hundred volumes were added by the Colorado group, and the academy supplied 6,000 volumes in addition to cash and securities. The Colorado State Board of Health earlier had contributed about 2,000 volumes to the academy. The state medical society and private contributions made possible subscription to foreign and domestic journals. These were supplemented by donations from members of the profession. The library is now jointly supported by the county and state medical societies, and its facilities are available to any member of the state society. It is housed in

the annex to the Metropolitan Building, Denver, and is maintained by dues of members plus a \$500 annual appropriation from the state society. All books and periodicals received by the state society are deposited, the total number of texts on hand in January 1938 being 14,983. Two hundred and sixty-three periodicals are received currently. During 1937, 9,029 patrons, more than three fourths of them physicians, visited the library, borrowing 8,105 items.

The Colorado State Board of Health Division of Maternal and Child Health sponsored postgraduate courses in obstetrics and pediatrics in collaboration with the committee advisory to the department of health of the state society, of which Dr. J. W. Ames is chairman. These courses were given in the northeastern and northern parts of the state during March and April 1937. Three pediatricians and three obstetricians gave ten two hour illustrated lectures over five weeks in four towns. Five lecture and clinic sessions were devoted to obstetrics and five to pediatrics. These were given from 4 to 10 p. m. on one day each successive week, one hour being allowed for dinner. The instructors and subjects were suggested by the Children's Bureau of the United States Department of Labor; two of the lecturers were members of the staff of the University of Colorado School of Medicine and four were faculty members of out of state universities. Courses were announced by post cards and letters distributed by the secretary of the state board of health, Dr. R. L. Cleere. Local physicians in the six counties where courses were given were responsible for local arrangements. They were invited to present interesting cases and to suggest problems for discussion. Of the 179 physicians licensed in this area, 114 enrolled, including some from five adjoining counties. The attendance at each meeting varied from twelve to eighteen, including a few public health nurses and medical students. There were no registration fees, the course being financed with federal funds.

The University of Colorado School of Medicine, in cooperation with the extension division of the university, formerly sent members of the faculty throughout the state to address component medical societies. This effort has now been taken over by the state medical society with the continued cooperation of the school of medicine. On request, members of the faculty are available for graduate programs. In the six years prior to 1933, annual clinics were given for medical graduates. At these clinics the average registration of physicians residing outside of Denver was 127, and in 1932 it was 106, thirty-one of whom came from towns with populations of less than 5,000. The school of medicine's annual clinics are now succeeded by the state society's midwinter clinics.

At the last annual meeting of the state medical society, three opening morning sessions were devoted to clinical pathologic conferences. Round table luncheon discussions were held each day at which a guest speaker presided. Six hundred and nine physicians of the 1,135 members of the state society attended. There are 1,923 physicians registered in Colorado. Approximately 85 per cent of the physicians practicing in Colorado are members of the state medical society.

UTAH

The committee on medical education and hospitals of the Utah State Medical Association consists of six physicians of Salt Lake City and six from other sections of the state. Dr. L. L. Daines, dean of the University of Utah School of Medicine, Salt Lake City, is chairman. During the first half of 1938 a member of the faculty of the medical school addressed each of six component medical societies throughout the state. Clinical pathologic conferences are held in four of the hospitals in Salt Lake City and in one Ogden hospital which members of the respective staffs may attend. The university library is used as a depository for books and periodicals received by the Salt Lake County Medical Society, which spends \$500 a year for maintenance. In turn, physicians may use the complete facilities of the medical school and general university library. The anatomic laboratory of the medical school provides cadavers for physicians desiring to perfect their operative technic or who are anxious to obtain additional basic science training.

At the 1937 annual meeting of the Utah State Medical Association an out of state obstetrician and pediatrician each conducted four illustrated lectures during two days. The program was financed with federal funds and was sponsored jointly by the Utah State Board of Health. Of 175 physicians who registered, sixty-five were from Salt Lake City and the remainder came from all but four of the twenty-nine counties of the state.

This year an out of state pediatrician is lecturing and giving infant conference demonstrations throughout Utah. From June 21 to August 20, fourteen or fifteen centers in five of the six health districts of the state are being visited. Health officers make local arrangements in each section. Personal conferences with physicians, consultations on request and lectures before

component medical societies are included. This effort is sponsored by the Division of Maternal and Child Health of the Utah State Board of Health and is financed with federal funds.

A representative from the division of venereal disease control of the state board of health met with the committee on syphilis and venereal disease of the state medical association in 1936 to consider a program for informing the public and the profession regarding advances in the knowledge of venereal diseases. Since then the board of health has conducted a public education campaign, but as yet similar consideration of the profession has not been given.

The annual meetings of the state medical association were attended by 310 physicians in 1937 and 316 in 1936. There are 443 members of the 567 physicians licensed in Utah.

OFFICIAL NOTES

RADIO BROADCASTS

The fourth series of programs broadcast in dramatic form portraying fictitious but typical incidents of significance in relation to health by the American Medical Association and the National Broadcasting Company entitled "Your Health" will begin Wednesday October 19 and run consecutively for thirty-six weeks. The program will be broadcast over the Blue network of the National Broadcasting Company each Wednesday at 2 p. m. eastern standard time (1 p. m. central standard time, 12 noon mountain time, 11 a. m. Pacific time).

These programs will be broadcast on what is known in radio as a sustaining basis; that is, the time is furnished gratis by the radio network and local stations and no revenue is derived from the programs. Therefore local stations may or may not take the program, at their discretion, except those stations which are owned and operated by the National Broadcasting Company.

The programs to be broadcast in the first group, together with their dates and their topics, are as follows:

October 19, What is Health?
October 26, Growing Strong.
November 2, Seeing and Hearing Well.
November 9, Healthier Boys and Girls.

The following is a list of the stations connected with the Blue network of the National Broadcasting Company, but no assur-

ance can be given as to how many of these stations will broadcast the program "Your Health":

Basic Blue Network

WOMAN'S AUXILIARY

The following officers have been elected by the Woman's Auxiliary to the American Medical Association for 1938-1939:

Officers:

President—Mrs. Charles C. Tomlinson, 5215 Jackson Street, Omaha.
President-Elect—Mrs. Rollo K. Packard, 6901 Paxton Avenue, Chicago.
First Vice President—Mrs. Frank N. Haggard, 615 East Olmos Drive, San Antonio, Texas.
Second Vice President—Mrs. David W. Thomas, 112 West Main Street, Lock Haven, Pa.
Third Vice President—Mrs. L. S. Merrill, 2761 Harrison Boulevard, Ogden, Utah.
Fourth Vice President—Mrs. J. R. Westaby, 621 Washington Avenue North, Madison, S. D.
Treasurer—Mrs. E. E. Fisher, Multnomah County Hospital, Portland, Ore.
Recording Secretary—Mrs. James A. Downing, 1246 Forty-Sixth Street, Des Moines, Iowa.
Corresponding Secretary—Mrs. James M. Woodward, 2132 South Twenty-Fourth Street, Lincoln, Neb.
Directors, one year—Mrs. Augustus S. Kech, 1221 Twelfth Avenue, Altoona, Pa.
Mrs. Carl A. Surran, 5 North Brunswick Avenue, Margate City, N. J.
Mrs. John W. Burns, 309 East Broadway, Cuero, Texas.
Mrs. Leslie J. Paul, 259 Douglas Street, Salt Lake City.

Directors, two years—Mrs. J. C. Geiger, 50 Ventura Avenue, San Francisco.

Mrs. E. W. Veal, 1936 San Marco Boulevard, Jacksonville, Fla.

Mrs. R. E. Mosiman, 2706 Tenth Avenue North, Seattle.

Chairmen of Standing Committees:

Archives—Mrs. Robert B. Homan, 1837 Grandview, El Paso, Texas.

Exhibits—Mrs. Ily R. Beir, 114 South Virginia Avenue, Atlantic City, N. J.

Finance—Mrs. James Blake, Hopkins, Minn.

Historian—Mrs. E. A. Barnes, Albany, Ky.

Hygeia—Mrs. James D. Lester, 268 Twenty-First Avenue South, Nashville, Tenn.

Legislation—Mrs. Arthur A. Herold, 1166 Louisiana Avenue, Shreveport, La.

Membership Award—Mrs. Herbert B. Henkel, 2135 Wiggins Avenue, Springfield, Ill.

Parliamentarian—Mrs. Rogers N. Herbert, Franklin Road, Nashville, Tenn.

Press and Publicity—Mrs. James P. Simonds, 25 East Walton Street, Chicago.

Printing and Supplies—Mrs. E. D. Lamb, Klamath Falls, Ore.

Program—Mrs. V. E. Holcombe, 1635 Quarrier Street, Charleston, W. Va.

Public Relations—Mrs. Henry Raile, 19 South Welcott Avenue, Salt Lake City.

Revisions—Mrs. James F. Percy, 1030 South Alvarado Street, Los Angeles.

MEDICAL ECONOMIC ABSTRACTS

EDUCATORS STUDY EDUCATION

Because some one is always comparing education and medicine, the conclusions of educators on our present system of education deserve some attention. The National Education Association of the United States and the American Association of School Administrators joined in appointing an Educational Policies Commission, which has recently presented its conclusions.¹ It is interesting to note at how many points the educational and the medical profession agree.

The educators criticize our present educational system because it has failed "to adapt the curriculum of the schools to the greatly varied abilities, interests and vocational outlooks of the students in attendance." In other words, pupils, like patients, need attention to their individual characteristics rather than mass treatment.

The invasion of business by the schools is criticized. Institutions that "are organized on a proprietary basis and are run for profit . . . have no place in our system of education."

The attitude of the educators that schools should not invade the field of the medical profession is shown in the following comment:

"Another example of an important service lying outside of the range of school activities is that of medical or surgical service. The schools may properly inquire concerning the physical well-being of their pupils, but the correction of remediable defects or the medical and surgical services should lie within the province of the public health agency or the private physician, surgeon or dentist."

Teachers and physicians are agreed in their opposition to uniform national programs. The report says:

"The nation is committed to a decentralized system of administration and control in education. . . ."

"Centralization in the control, administration and financing of education is very apt to lead to a mediocre school system and a lack of progressive development of the program of public education."

Even when federal aid is urged for certain phases of education, this is accompanied by opposition to national control of education. The system of federal control based on the "matching by the state of the moneys distributed to them by the federal government" is denounced as an "insidious type of control."

Finally, the educators, no less than the members of the medical profession, insist that educational matters and even "administrative details should always be left to the professional executive."

SICKNESS INSURANCE IN NORWAY

The provisions of the sickness insurance law in Norway are described in the Monthly Labor Review of the United States Department of Labor (46:1122 [May] 1938) on the basis of data furnished by the American consulate at Oslo, Norway.

The basic law establishing the present system was enacted in 1930 and has been revised five times since, the latest revision being made on June 17, 1937. The law provides for both compulsory and voluntary insurance. The administration is largely in the hands of municipal funds, of which there were 759 in 1936; there were also thirty-four recognized private funds. All wage earners of 15 years of age or over with an annual income of less than 6,000 kroner (a little less than \$1,500) must belong to an insurance fund or an authorized sick-benefit fund. Of the total contributions required, the insured pays six tenths, the employer one tenth, the state two tenths and the municipality one tenth. The contributions of individuals vary according to six wage classes, and the cash benefits vary in the same manner.

Medical care may be given either in the form of free medical attendance by physicians with whom the funds have contracts

1. The Structure and Administration of Education in American Democracy, by the Educational Policies Commission of the National Education Association of the United States and the American Association of School Administrators, Washington, D. C., 1938.

or as a refund to the members for medical care in accordance with rates fixed by the crown. The members have freedom of choice of physician. If the fee charged is higher than that allowed by the insurance funds, the member must pay the difference between the authorized fee and that charged by the physician consulted. All compulsory and voluntary members of the sickness insurance fund and their dependents, including children and foster children under 16 years of age, are entitled to benefits regardless of age.

The central administrative body is a state insurance institution under the direction of a board of five members. The expenses of the institution in connection with the administration of sickness insurance are paid by the state. In 1936 there were 896,553 members of sickness insurance funds, of whom 755,084 were under the compulsory plan and 141,469 were voluntary members. In 1936 there were 249,791 cases of sickness among these members for which sickness benefits were paid, which works out at an average of about one case of sickness for every 3.5 persons.

MATERNAL HEALTH AND THE ILLINOIS STATE MEDICAL SOCIETY

When the Social Security Act became a law in 1935 there were three sections referable to health, namely maternal and infant welfare, aid to crippled children and the expansion of the general health program. In all of these divisions the United States Children's Bureau and the United States Public Health Service, charged with their administration, created advisory committees of medical and public health authorities and encouraged the several states to procure active cooperation from the state medical societies. How such cooperation can be worked out is well exemplified by the report of the Maternal Welfare Committee of the Illinois State Medical Society.¹ In Illinois the governor appointed the Committee of Maternal Welfare, and the state director of public health, the chief of the state department bureau of child welfare and public health nursing and the chairman of the educational committee of the Illinois State Medical Society were members, under the chairmanship of the professor of obstetrics at the University of Illinois College of Medicine.

Under this committee refresher courses in obstetrics and pediatrics were arranged to be presented before many county medical societies under the supervision of the educational committee of the state medical society. A field consultant for the Committee of Maternal Welfare was appointed, and he arranged with many county medical societies for the development of these courses. In addition, postgraduate courses in obstetrics and pediatrics were conducted at the University of Illinois College of Medicine during the summer of 1937. The state medical society Maternal Welfare Committee was developed with one member from each of the eleven councilor divisions.

The state medical society Maternal Welfare Committee functioned under four major objectives, namely the refresher courses, an educational program for the public on antepartum care, sponsorship by organized medicine of the health activities under the Social Security Act and furtherance of the summer postgraduate courses. District meetings were held in each district and efforts were made to bring to the lay public the true facts about maternal mortality in the United States as compared with other countries. In this connection it was pointed out that, in the United States, deaths occurring during the puerperal state are invariably classed as maternal deaths including criminal abortions, deaths from intercurrent infections during pregnancy and deaths due to other causes, whereas in many countries the actual causes of such deaths are properly reported under their several classifications.

The Committee on Maternal Welfare is embarked on an eight point program including emphasis on adequate antepartum care, greater attention to eugenics rather than to birth control,

1. Illinois M. J. 74: 44 (July) 1938.

refresher courses, studies on the preventability of maternal, fetal and early infant deaths, in Illinois a physicians' speakers' service for lay groups in each county, public meetings in each county, routine Wassermann tests for all prospective mothers and cooperation with women's groups.

This program is projected over a five year period and it is believed that it will result in better maternal and infant health in the state of Illinois with a maximum participation by practicing physicians and with the cooperation of official health agencies and citizens' groups, especially women's groups.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Hospital News.—Dr. Quitman U. Newell, St. Louis, conducted a gynecologic operative clinic at the Hillman Hospital, Birmingham, August 1.

ARKANSAS

Society News.—The Southeast Arkansas Medical Society was recently addressed at McGehee by Drs. Lee Vallette Parmley on work for crippled children and Grady W. Reagan, diagnosis of diseases of the upper urinary tract; both are from Little Rock. There was also a discussion on the study of medical care.—At a meeting of the Lawrence County Medical Society in Hardy recently the speakers included Drs. Hubert K. Turley, Memphis, Tenn., on pyelitis; John J. Monfort, Batesville, local anesthesia, and John L. Jelks, Memphis, rectal fistulas.—Drs. Davis W. Goldstein and Everett C. Moulton, both of Fort Smith, discussed syphilis and syphilitic manifestations in ophthalmology respectively before the Benton County Medical Society in Rogers August 11.—At a meeting of the Independence County Medical Society in Batesville August 8 Dr. Finis Q. Wyatt, Corpus Christi, Texas, spoke on "Acute Suppurative Empyema."—Dr. Clyde D. Rodgers, Little Rock, discussed antepartum care before the Fourth Councilor District Medical Society in Warren August 18.

CALIFORNIA

Society News.—The staff of the Weimar Joint Sanatorium, Weimar, presented a symposium on compression therapy in the treatment of tuberculosis at a recent meeting of the Placer County Medical Society.—The Ventura County Medical Society was addressed recently by Dr. Carl E. Ebert, Los Angeles, on "Pitfalls for the General Practitioner in the Practice of Urology."—At a dinner meeting of the Hollywood Academy of Medicine in Hollywood, August 11, Capt. Basil Webb, big game hunter and adventurer, spoke on "Fetishes, Facts and Fancies of Savage Medicine."—Dr. Ko K. Chen, Indianapolis, addressed a special meeting of the San Francisco County Medical Society September 15 on "Digitalis-like Preparations." The society was addressed September 13 by Drs. William L. Rogers on "Tuberculous Bronchitis—Its Role in Collapse Therapy"; George B. Miller, "Early Diagnosis and Control of Tuberculosis," and Sidney J. Shipman, "Pneumothorax and the General Practitioner"; all are of San Francisco.—At a meeting of the Los Angeles Society of Neurology and Psychiatry September 21, Drs. Rupert B. Raney and David L. Reeves, Los Angeles, discussed "Acute Pneumococcus Metastatic Spinal Epidural Abscess" and "Glioma of the Optic Nerve" respectively.

Laboratory for Study of Sylvatic Plague.—The University of California will establish a laboratory for sylvatic plague with a gift of \$24,000 from the Rosenberg Foundation of San Francisco. Fourteen thousand dollars will be used to construct a building and the remainder for research and personnel. The laboratory will be staffed by the Hooper Foundation for Medical Research. Work will be concentrated on rodent fleas. Both the state and the university have been active in the campaign against sylvatic plague for years. Interested agencies have formed a Sylvatic Plague Committee, which has devoted itself to the collection of evidence of sylvatic

plague everywhere on the American continent and is taking measures to combat it. Anti plague serum is being kept constantly on hand at the Hooper Foundation. Four nonfatal human cases have been bacteriologically proved thus far. The Hooper Foundation has counted thirteen rodents and rodent varieties that suffer from spontaneous plague, the list including squirrels, marmots, chipmunks, prairie dogs, mice and rats. The West Coast became infected in the course of the pandemic of 1894, which originated in Hongkong. It is assumed that rats conveyed the seed to the shores of California and spread it to the squirrels. It has now reached Montana and appears to be working eastward.

CONNECTICUT

Personal.—Dr. William Sherman Randall has been appointed health officer of Shelton to complete the unexpired term of the late Dr. J. Eugene Black.

Childs Memorial Research Fund.—The major portion of the income of the Jane Coffin Childs Memorial Fund for Medical Research will be used for the next three years to finance a study of cancer at Yale University, it was announced in the fund's first annual report. In addition, grants-in-aid have been and will be made for cancer research in other institutions in this country and abroad. The primary purpose of the fund at present is to support research into the causes, origins and treatment of cancer, with emphasis on the causes and origins. Therapeutic investigations have been considered from the point of view of their contribution to knowledge of causes and origins. When the fund was established in 1937 the amount of the principal was appraised at \$3,343,556.

FLORIDA

Society News.—Dr. James H. Putman, Miami, discussed "Pain in the Right Hypochondrium, Some Factors in Its Production," before the Dade County Medical Society August 2.—At a meeting of the DeSoto-Hardee-Highlands County Medical Society in Sebring recently Dr. Allen A. Poucher, Wauchula, discussed symbiosis.

Personal.—Dr. James M. Hoffman, Pensacola, president of the Escambia County Medical Society, presented Dr. Juriah Harris Pierpont, Pensacola, with a scroll signed by members of the society, August 2, to observe his completion of fifty years' practice in the county.—Dr. Henry C. Lochte, Bay Pines, has retired as chief of the outpatient division at the Veterans' Administration Facility, it is reported; he has held the position since 1933.—Dr. James Maxey Dell Sr., Gainesville, has been appointed district deputy grand exalted ruler of the Benevolent and Protective Order of Elks for the Florida north area.

GEORGIA

Personal.—Dr. Luther A. Brendle, Clinton, Tenn., has been appointed health officer of Dodge County, succeeding Dr. Johnnie L. Gallemore, Eastman, resigned.—Dr. Frank K. Boland has been elected president of the Atlanta Historical Society.

Chattahoochee Valley Meeting.—Dr. John S. Turberville, Century, Fla., was elected president of the Chattahoochee Valley Medical Association at its annual meeting at Radium Springs, Albany, July 14. Drs. Guy J. Dillard, Columbus, and Clarence R. Bennett, Eufaula, Ala., were selected as vice presidents. Dr. Frank K. Boland, Atlanta, will serve two more years to complete his five year term as secretary-treasurer. Dr. James G. Lyerly, Jacksonville, Fla., delivered the W. J. Love memorial address on "Prefrontal Lobotomy."

ILLINOIS

Society News.—The Henry County Medical Society was addressed in Kewanee September 8 by Dr. Charles E. Gallo-way, Evanston, on obstetrics. A paper on pediatrics was read by Dr. John A. Bigler, Highland Park.—Dr. M. Herbert Barker, Chicago, discussed "Nephritis and Edema" before the Kankakee County Medical Society at Kankakee September 8.—At a meeting of the county medical society at Effingham, September 13, Dr. Frank Deneen, Bloomington, spoke on "Diagnosis and Medical Treatment of Liver and Gallbladder Conditions."—Dr. Herbert E. Schmitz, Chicago, discussed gynecology before the Coles-Cumberland County Medical Society at Mattoon September 14.—The Marion County Medical Society was addressed at Centralia September 15 by Dr. Arthur H. Conley, Chicago, on "Injuries to and Fracture of the Bones."—At a meeting of the Peoria

County Medical Society at Peoria September 20 Drs. Ford K. Hick and Conrad S. Sommer, Chicago, will discuss various aspects of internal medicine. — Dr. Raymond A. Tearnan, Decatur, will address the Christian County Medical Society September 21 on "Endocrine Factors in Various Gynecologic Disorders." — A symposium on pediatrics and obstetrics will be sponsored by the Joe Davis and Carroll County Medical Societies at Elizabeth September 21; the speakers will be Drs. Arthur H. Parmelee, Oak Park, and William F. Mengert, Iowa City, on "Diseases of the Newborn" and "Treatment of Prolonged Labor" respectively.

Chicago

Dr. Moss Retires. — Dr. Daniel B. Moss, chief medical officer of the Chicago, Burlington and Quincy Railroad since 1924, retired on pension September 15 after forty years' service with the road. He will be succeeded by Dr. Onis H. Horrall, general surgeon for the line, who has been appointed chief surgeon in charge of all surgical work of the company. Born in Palmyra, Mo., Dr. Moss graduated at the Missouri Medical College, St. Louis, in 1896 and engaged in the private practice of medicine in Hannibal, Mo. He became associated with the medical department of the Burlington in St. Joseph, Mo., June 7, 1898. In 1903 he was transferred to the general headquarters at Chicago and in April 1924 was appointed chief medical officer. Dr. Horrall graduated at Rush Medical College in 1920 and entered private practice in Casper, Wyo. He was appointed division surgeon for the Burlington at Sheridan, Wyo., in 1922, moving to Chicago in 1924. He has served as general surgeon for the Burlington since Oct. 13, 1937. Dr. Raymond B. Kepner, who joined the company's medical department in St. Joseph, Mo., in January 1920, has been appointed medical officer of the company and medical director of the relief department. He graduated at Rush in 1917.

INDIANA

Division of Nutrition Established. — The bureau of maternal and child health of the state department of health established a division of nutrition August 1 with Miss Estelle Nesbitt, New Richmond, in charge. For the present it is planned to confine the activities of the nutrition service for the most part to cooperation with the demonstration branch of the dental health program in district health unit number 4, which includes the counties of Switzerland, Ohio, Dearborn, Ripley and Jefferson. During November nutrition institutes will be conducted for public health nurses. Work of the new division will include study of the prevalence of nutritional diseases in the state and cooperation with local health agencies in solving the nutritional needs of the community. Special attention will be paid to expectant mothers. Representatives of various agencies in the state make up an advisory council to the director of new division.

IOWA

Society News. — At a meeting of the Upper Des Moines Medical Society in Okoboji August 4, the speakers were, among others, Drs. William D. Paul, Iowa City, on "Recent Advances in the Treatment of Diabetes"; Albert S. Welch, Kansas City, Mo., "Intestinal Protozoa"; Archibald F. O'Donoghue, Sioux City, "Fractures of the Hip Treated by Internal Fixation"; Lealdes M. Eaton, Rochester, Minn., "Pain Characteristic of Various Neurologic Diseases"; Hiram Winnett Orr, Lincoln, Neb., "Prevention and Control of Wound Infection and Interpretation of Asepsis," and Louis A. Buie, Rochester, Minn., "Anal Pruritus."

KANSAS

Society News. — The Sedgwick County Medical Society held its twelfth annual golf tournament September 16; a new trophy was presented this year by Mr. Mac Cahal, Chicago, formerly executive secretary of the society and now executive secretary of the Inter-Society Committee for Radiology. — Dr. Bertrand I. Krehbiel, Topeka, discussed a case of tetanus with recovery in a child 21 months old before the Shawnee County Medical Society in Topeka September 6.

KENTUCKY

State Medical Meeting in Louisville. — The Joseph N. McCormack Memorial Meeting of the Kentucky State Medical Association will be held in Louisville October 3-6. A feature of the meeting will be the unveiling of a plaque and dedication of the new building of the state board of health as a memorial to the late Dr. McCormack, known as "the father of

public health, preventive medicine and medical organization in Kentucky." The guest speakers will be:

Dr. Frank H. Lahey, Boston, Management of Lesions of the Colon and Rectum.
Dr. Ernest E. Irons, Chicago, Lobar Pneumonia.
Dr. Daniel C. Elkin, Atlanta, Ga., Cholecystitis—When and If Operable.

Dr. Harry Stack Sullivan, New York, president of the William Alanson White Psychiatric Foundation, will be the speaker at the annual banquet Wednesday evening, when the president of the association, Dr. William E. Gardner, Louisville, will give his official address. Dr. Clark Bailey, Harlan, will give the annual oration in medicine and Dr. Francis M. Massie, Lexington, the oration in surgery. The annual golf tournament will be held at the Louisville Country Club Monday October 3; there will also be a trapshooting contest at the Highland Park Gun Club the same day.

MAINE

Society News. — At a meeting of the Aroostook County Medical Society in Houlton recently, the speakers included Dr. Delmer Allan Craig, Bangor, on "The Standardized Hospital and Its Benefit to Doctor and Patient." — Among others, Dr. Robert H. Aldrich, Boston, addressed the Piscataquis, Aroostook, Somerset, Kennebec and Penobscot county medical societies at a joint meeting July 21; his subject was "Aniline Dye Treatment of Burns."

MASSACHUSETTS

Dr. Chadwick Resigns as State Health Commissioner. — Dr. Henry D. Chadwick, since 1933 health commissioner of Massachusetts, has resigned to become medical director of the Middlesex County Sanatorium at Waltham, according to the *New England Journal of Medicine*. A graduate of Harvard University Medical School, Dr. Chadwick practiced in Waltham from 1896 to 1905, then was superintendent of the Vermont Sanatorium for Tuberculosis, Pittsford, 1907-1909, holding a similar post with the Westfield (Mass.) State Sanatorium for tuberculous children from 1909 to 1929, when he went to the Detroit department of health as tuberculosis controller. He served as president of the American Sanatorium Association in 1930, and of the Michigan Tuberculosis Association, 1932 and 1933.

MICHIGAN

Examinations for State Positions. — The Michigan Civil Service Department announces that examinations will be held in the immediate future for several medical positions. The positions open are resident institution physician, resident hospital roentgenologist, hospital physician, sanatorium physician and public health physician, at salaries ranging from \$150 to \$400 a month, less maintenance where it is provided. Those interested are urged to communicate at once with the civil service department, 508 North Grand Avenue, Lansing, for application blanks and further information as to the requirements.

MISSOURI

Annual Fall Conference. — The sixteenth annual fall clinical conference of the Kansas City Southwest Clinical Society will be held at the Municipal Auditorium, Kansas City, October 3-6. Guest speakers will include:

Dr. Thomas Leon Howard, Denver, Colo., How Should the General Physician and Surgeon Evaluate Bladder Symptoms in His Patients?
Dr. William J. Diekmann, Chicago, Treatment of Nonconvulsive Toxemias of Pregnancy.
Dr. George T. Pack, New York, Indications for Surgery and Indications for Irradiation in the Treatment of Cancer.
Dr. Isidor S. Ravdin, Philadelphia, Problems of Long Standing Gallstone Disease.
Dr. William D. Sansum, Santa Barbara, Calif., The Causes, Dangers and Treatment of Overweight.
Dr. Elmer L. Sevringhaus, Madison, Wis., Diagnosis of Causes of Menstrual Disturbances.
Dr. Lawrence Reynolds, Detroit, Passage of Foodstuffs Through the Gastrointestinal Tract as Determined by Chemical and Roentgenologic Methods.
Dr. Frank R. Ober, Boston, Management of Lamé Joints as a Result of Trauma.
Dr. Chester A. Stewart, Minneapolis, Evolution of Tuberculosis in Children.
Dr. Louis J. Karnosh, Cleveland, Neuritis, Neuralgia and Neurosis.
Dr. James B. Costen, St. Louis, Mandibular Joint Syndrome.
Dr. Grady E. Clay, Atlanta, Ga., Pathologic Changes in the Fundus Oculi in Essential and Malignant Hypertensive Disease.
Dr. Arthur E. Hertzler, Halstead, Kan., The Götter Heart.

Round table luncheons will be held each day. A feature of the meeting Monday evening will be the discussion of a "mys-

tery case." The history, physical examination and laboratory findings of a baffling case, taken from the records of a large eastern hospital, will be published in the program issue of the *Kansas City Medical Journal*. Every one is urged to read it carefully. A group of selected "key" men will be asked to occupy seats on the platform of the Little Theater. In addition, any physician present will be allowed to discuss the case presented. No one in the entire audience, except the chairman, will know the final diagnosis of the case. Men from the various specialties will be called from the audience for discussion.

MONTANA

Personal.—Dr. Harry V. Gibson, health officer of the Eau Claire, Wis., county health unit, has been appointed health officer of Great Falls and Cascade County, it is reported.

NEVADA

State Medical Meeting at Reno.—The thirty-fifth annual meeting of the Nevada State Medical Association will be held in Reno September 23-24 at the Bowers Mansion, under the presidency of Dr. Harry W. Sawyer, Fallon. The speakers will be:

- Dr. Albert H. Rowe, Oakland, Calif., Chronic Allergy in Medical Practice.
- Dr. Alson R. Kilgore, San Francisco, Postoperative Distention—Prevention and Treatment.
- Dr. Miley B. Wesson, San Francisco, Kidney Infections—Pyelographic Diagnosis.
- Dr. Ruggles A. Cushman, Talmage, Calif., Mental Disease as Met in General Practice.
- Dr. Philip King Brown, San Francisco, Complications of Pneumonia.
- Dr. Ernst Gehrels, San Francisco, Gastric and Duodenal Ulcer—The Case Against Gastro-Enterostomy.
- Dr. William H. Daniel, Los Angeles, Common Proctologic Disorders.
- Dr. Albert R. Da Costa, Reno, New Anesthetics and Methods; Carbon Dioxide Absorption with Cyclopropane.
- Dr. Lemuel R. Brigman, Reno, Congenital Syphilis: Intracscalp Method of Administering Sulfarsphenamine.

NEW JERSEY

Society News.—Dr. Harold D. Harvey, New York, will address the Bergen County Medical Society, Englewood, September 20, on "Use and Abuse of Sulfanilamide."—Dr. William T. Lemmon, Philadelphia, addressed the Gloucester County Medical Society, Woodbury, September 15, on "Common Diseases Relieved by Surgical Operations on the Sympathetic Nervous System," and Dr. Edward Zeh Hawkes, Newark, president-elect of the Medical Society of New Jersey, "The Objectives and Administrative Policies of the Medical Society of New Jersey."

Opening of Squibb Research Institute.—The new Squibb Institute for Medical Research at New Brunswick will be officially opened October 11 with a special program. Mr. Carleton H. Palmer, president of E. R. Squibb and Sons, will give an address of welcome and Dr. John F. Anderson, director of the biologic laboratories, an address on the institute. Dr. George A. Harrop, newly appointed director of the institute, will introduce the following guest speakers:

- Dr. George R. Minot, Boston, Clinical Investigation.
- Dr. Russell M. Wilder, Rochester, Minn., Industrial Laboratories and Clinical Research.
- August Krogh, professor of animal physiology, University of Copenhagen, Denmark, Biology and Medicine in Cooperation.
- Dr. Abraham Flexner, Princeton, N. J., The Usefulness of Useless Knowledge.

NEW YORK

District Meeting.—The Seventh District Branch of the Medical Society of the State of New York will hold its annual meeting at the Oak Hill Country Club, Rochester, September 22. Dr. William N. MacArtney, Fort Covington, author of "Fifty Years a Country Doctor," will make the principal address, and the film "Birth of a Baby" will be shown. The afternoon session will be made up of panel discussions with the following subjects and leaders: Drs. James H. Sterner, Rochester, "Rational Drug Therapy"; Abraham H. Aaron, Buffalo, "Gastrointestinal Problems"; Albert D. Kaiser, Rochester, "Problems in Children," and David B. Jewett, Rochester, "Pneumococcic Infections."

New York City

Health Safeguards at World's Fair.—Plans for health and medical care at the New York World's Fair include ten first aid stations, a corps of physicians and surgeons, about 100 nurses, ten ambulances and a mobile x-ray unit, according to an announcement.

Personal.—Thomas J. Duffield, registrar, bureau of records, New York City Department of Health, has been appointed a delegate to the International Commission for the Decennial Revision of the International Nomenclature of Diseases, which opens in Paris October 3.

Attempt to Curb Boat Whistles.—The Maritime Association of the Port of New York recently adopted a resolution authorizing its committee on rivers, harbors and piers to communicate with owners and operators of craft in the harbor to eliminate unnecessary whistling on their vessels and excessive noise along the waterfront.

University News.—The Crocker Institute for Cancer Research of Columbia University has moved from its building at One Hundred and Sixteenth Street and Amsterdam Avenue to new quarters on two floors of the school of medicine at the Columbia-Presbyterian Medical Center, One Hundred and Sixty-Eighth Street and Fort Washington Avenue. The institute had been in the old building since its founding in 1913.

Symposium on Ulcerative Colitis.—The department of medicine, New York Post-Graduate Medical School, announces a symposium on chronic ulcerative colitis to be held September 23 at the Erdmann Auditorium. Dr. Philip Manson-Bahr, London School of Hygiene and Tropical Medicine, will be the guest of honor and will speak on "Differential Diagnosis of Ulcerative Colitis and the Dysenteries." Other guests on the program will be Drs. Moses Paulson, Baltimore, speaking on "Diagnostic Methods in Ulcerative Colitis," and Richard B. Cattell, Boston, on "Surgical Treatment of Ulcerative Colitis." Dr. Jacob Arnold Bargen, Rochester, Minn., will conduct a clinic.

NORTH CAROLINA

Changes in Health Officers.—Dr. Clarence H. White, Burnsville, district health officer for Avery, Watauga, Yancey and Mitchell counties, has been appointed health officer of a new unit in Catawba County, it is reported. Dr. Robert R. King, Boone, has been appointed district health officer in a new district made up of Ashe, Alleghany and Watauga counties.

Society News.—Dr. Claiborne T. Smith, Rocky Mount, addressed the Edgecombe-Nash Counties Medical Society August 10 in Tarboro on "Bromide Intoxication."—Drs. Richard B. Dunn and Opie Norris Smith, both of Greensboro, addressed the Guilford County Medical Society August 4 on "Modern Methods of Resuscitation of the Newborn" and "Bromide Poisoning" respectively.—Dr. Thomas T. Stixrud, formerly of North Carolina and a missionary to the Belgian Congo for many years, addressed the Buncombe County Medical Society, Asheville, August 17, on sleeping sickness.

OHIO

Regional Graduate Lectures.—The second series of graduate lectures in a five year educational program sponsored by the Ohio State Medical Association opened September 7 in Mansfield and Dayton and September 8 in Zanesville. Sessions in region E will be alternated between Dayton and Springfield. There will be eight sessions with two lectures each in each group, the series ending early in December. Subjects to be covered in all sessions are the clinical aspects of arteriosclerosis, treatment of early syphilis, pneumonia, diabetes, intestinal obstruction, common lesions of the cervix, prophylaxis and treatment of common contagious diseases, tuberculosis in infancy, common psychoses, cancer of the breast, antepartum and postpartum care, infections of the urinary tract, angina pectoris and coronary thrombosis, fungus infections of the skin and arthritis.

OKLAHOMA

Society News.—The Pittsburg County Medical Society was addressed June 17 by Drs. Frederic G. Dorwart and Edward Halsell Fite, Muskogee, on statistical studies of diuretics and urology in children respectively.

Graduate Study in Obstetrics.—The Oklahoma State Medical Association is sponsoring a two year plan for graduate teaching in obstetrics in cooperation with the Commonwealth Fund of New York and the state department of health. The state has been divided into twelve teaching circuits, five cities to a circuit. The course will consist of a lecture each week for ten weeks in each town. Dr. Edward N. Smith, Oklahoma City, will be the lecturer.

OREGON

State Medical Election.—Dr. Charles E. Hunt, Eugene, was chosen president-elect of the Oregon State Medical Society at the annual session at Mount Hood Timberline Lodge August 24-27 and Dr. Charles E. Sears, Portland, became president. Vice presidents elected were Drs. Louis P. Gambee, Portland; Frank L. Ralston, La Grande, and George E. Henton, Portland. Dr. Morris L. Bridgeman, Portland, was reelected secretary.

Vender of Medicinal Tea Enjoined.—Mary Rockwell of Portland, operating under the trade name of the Rhein Gold Tea Company, was enjoined from engaging in the illegal practice of medicine in an action recently instituted by the state board of medical examiners in the circuit court of Oregon, fourth judicial district, department 2. While the defendant claimed that she merely sold a food product in the form of a tea brewed from certain herbs possessing health-giving properties, the evidence indicated that she diagnosed ailments of persons from a study of what the court referred to as "urine analysis charts" and prescribed one or more of the fifteen teas she sold. She attempted to treat mastoiditis, tumors, diabetes, epileptic fits, constipation, kidney disease, headaches and gynecologic disorders by prescribing drugs said by the court to be largely cathartic. The defendant employed no physicians at the time this action was instituted but on prior occasions she had employed one or two for a few weeks. These physicians, however, severed their connection with the defendant's business. While the court thought it immaterial whether or not the defendant benefited any person for whom she prescribed, it was difficult for the court to conclude from the evidence that the "urine analysis charts" showed physical deficiencies that could be corrected by products sold by the defendant. This case, according to the attorney for the Oregon State Board of Medical Examiners, is the first instituted by the board under an amendment to the medical practice act adopted in 1937 specifically authorizing the board to institute proceedings to enjoin the illegal practice of medicine.

PENNSYLVANIA

State Medical Meeting at Scranton.—The eighty-eighth annual session of the Medical Society of the State of Pennsylvania will be held in Scranton October 3-6, under the presidency of Dr. Frederick J. Bishop, Scranton. Guest speakers who will address general and section meetings include:

- Dr. Frank E. Adair, New York, Cancer.
- Dr. Robert L. Levy, New York, Therapeutic Aspects of Cardiac Pain.
- Dr. Maxwell Finland, Boston, Control of Pneumonia.
- Dr. Julius L. Wilson, West Haven, Conn., Pathology, Symptoms and Diagnosis of Pulmonary Tuberculosis.
- Dr. Henry A. Christian, Boston, Certain Clinical Aspects of Chronic Bright's Disease.
- Dr. Shields Warren, Boston, A Consideration of the Recent Important Discoveries Concerning the Etiology, Pathologic Physiology and Pathology of Diabetes.
- Dr. Perrin H. Long and Eleanor A. Bliss, Sc.D., Baltimore, Further Observations upon the Use of Sulfanilamide and Its Derivatives in the Treatment of Infectious Diseases.
- Dr. Abraham H. Aaron, Buffalo, Medical Measures of Value in the Treatment of Gastrointestinal Diseases.
- Dr. Richard H. Overholt, Brookline, Mass., Recent Advances in the Treatment of Pulmonary Tuberculosis.
- Dr. Harvey B. Stone, Baltimore, Surgery of the Colon.
- Dr. Samuel J. Kopetzky, New York, Management and Treatment of Orogenic Meningitis.
- Dr. Cecil S. O'Brien, Iowa City, The Extraction of Senile Cataract.
- Dr. Josephine B. Neal, New York, Treatment of Meningitis.
- Emerson R. Sausser, D.D.S., Philadelphia, The Problem of Dental Diseases Affecting the Child.
- Dr. Charles F. McKhann, Boston, Tissue Extracts and Blood Coagulation.
- Dr. Frank J. Eichenlaub, Washington, D. C., Transfusion Syphilis.
- Dr. Philip W. Brown, Rochester, Minn., The Mutual Interchange of Intestinal and Urinary Signs.
- Dr. Benjamin P. Watson, New York, Present Attainment and Future Hope—An Obstetrical Review.

Round table conferences have been arranged on cancer, cardiovascular diseases, pneumonia, tuberculosis, nephritis and diabetes, in which several of the guests will participate. The section on pediatrics will have a panel discussion of endocrinology in childhood and the section on urology a symposium on chemotherapy.

Philadelphia

Society News.—At the first fall meeting of the Philadelphia County Medical Society, September 21, Dr. Chauncey L. Palmer, Pittsburgh, chairman of the committee on public health legislation, Medical Society of the State of Pennsyl-

vania, will make an address entitled "Whither Medicine?"—A symposium on biliary disease was presented at a meeting of the North End Medical Society and the North Branch of the Philadelphia County Medical Society September 15 by Drs. William A. Swalm, Isidor S. Ravdin and Henry L. Boekus.

Pittsburgh

Research on Stream Pollution.—The American Iron and Steel Institute has recently founded a fellowship at Mellon Institute of Industrial Research to study the problem of preventing stream pollution by waste liquors from such operations as "pickling," in which metals are treated with acids. The object of the research will be to treat or process the waste material so as to render it safe for discharge into streams and to recover from it chemicals that can be used again. Willard W. Hodge, M.A., professor of chemical engineering, University of West Virginia, Morgantown, is on leave of absence for a year to head the investigation at Mellon Institute.

TENNESSEE

Society News.—Dr. Paul H. Ringer, Asheville, N. C., addressed the Greene County Medical Society, Greenville, July 12, on "Early Diagnosis and Treatment of Tuberculosis" and Dr. Jesse B. Naive, Knoxville, "The Part Played by Institutional Care in a Tuberculosis Control Program."—Drs. Harold J. Starr and John W. Hocker, Chattanooga, addressed the Chattanooga and Hamilton County Medical Society August 4 on "Diarrhea in Children" and "Diagnosis and Treatment of the More Common Skin Conditions in Children" respectively.—Among speakers at a meeting of the Memphis and Shelby County Medical Society July 5 were Drs. Nicholas Gotten on the use of mandelic acid in epilepsy and Charles G. Andrews, cancer of the breast; both are of Memphis.

TEXAS

Committee on Industrial Health Appointed.—Dr. Charles M. Aves, Houston, has been appointed chairman of a new committee on industrial health of the Texas State Medical Association. Members of the committee are Drs. William P. Lowry, Wichita Falls; Ross B. Trigg, Fort Worth; George Sladczyk, Port Arthur, and Harry A. Haverlah, Palestine.

Hospital News.—Plans have been announced for a forty-bed isolation hospital in connection with the El Paso City-County Hospital, to be built at a cost of about \$50,000 financed in part with PWA funds. The building will be in modified Spanish style of one story. There will be a special department for patients with poliomyelitis.—The Methodist Hospital, Fort Worth, is to be renamed the Harris Memorial Hospital in memory of the late William H. Harris, father of the medical superintendent, Dr. Charles H. Harris. The hospital has received as an endowment the Harris Clinic and Hospital, valued at \$200,000, notes totaling \$153,000 held against the hospital by Dr. Harris, and a share in the Harris estate at his death estimated at from \$250,000 to \$500,000, according to *Hospitals*.—Drs. I. Sellers Moore, formerly of Ozona, and Lee Alton Absher, formerly of Portland, Tenn., have opened a \$30,000 hospital at Midland. It contains five rooms for patients, an operating room and various treatment rooms, with x-ray and ultraviolet ray equipment.

VIRGINIA

Society News.—Dr. W. Ambrose McGee, Richmond, was the guest speaker before the Fourth District Medical Society in South Hill August 16; his subject was "Prophylaxis and Early Recognition of Allergic Diseases of Childhood." Other speakers were Drs. Ruth S. Mason-Grigg, Petersburg, on "Treatment of Diabetes"; Philip Jacobson, Petersburg, "Complications of Diabetes," and William R. Jordan, Richmond, "General Care of Diabetes."—Dr. John M. Meredith, Charlottesville, addressed the Augusta County Medical Society, Waynesboro, August 3, on "Head Injuries."

Personal.—Dr. Meade Stith Brent of the staff of the Central State Hospital, Petersburg, has been appointed superintendent to succeed Dr. Hugh C. Henry. Dr. Henry was recently appointed state hospital director.—Dr. James Nicholas Dudley, formerly of Eastville, has been appointed health officer for the Farmville district, made up of Prince Edward, Buckingham and Nottoway counties.—Dr. Benjamin Roscoe Gary, Newport News, was presented with a silver service recently as a mark of appreciation from his patients.

Dr. Gary has practiced forty-seven years in Newport News. He graduated from the University of Maryland School of Medicine, Baltimore, in 1891.

WEST VIRGINIA

Personal.—Dr. Edwin Cameron, Baltimore, has been appointed health officer of Monongalia County.—Dr. Robert L. Hunter, Whitesville, health officer of Boone County, has been placed in charge of a new Coal River District that includes Boone and Lincoln counties.

PUERTO RICO

Personal.—Dr. Eduardo Garrido Morales has been reappointed by Governor Winship commissioner of health of Puerto Rico for a term of four years.

GENERAL

Changes in Status of Licensure.—The New Jersey Board of Medical Examiners recently reported the following actions:

Dr. Ernest Casini, Garfield, license revoked April 20.

Dr. Joseph F. Iuliani, Newark, license restored June 15.

The New York State Board of Medical Examiners reported the following action:

Dr. Sigmar K. Reinholdt Hilfer, whose last known address was 5 Riverside Drive, New York, license revoked May 20, on the charge of fraud and deceit in the practice of medicine.

The Oklahoma State Board of Medical Examiners recently reported the following action:

Dr. Mark White, Chicago, license issued by reciprocity from Iowa revoked June 9 for unprofessional conduct.

Mississippi Valley Tuberculosis Meeting.—The silver anniversary meeting of the Mississippi Valley Tuberculosis Conference and the Mississippi Valley Sanatorium Association will be held in St. Louis September 21-24 under the presidency of Dr. Edward A. Meyerding, St. Paul, for the conference and of Dr. Vera V. Norton, Cincinnati, for the association. Among speakers at various sessions will be:

Dr. Herman E. Hilleboe, St. Paul, Analysis of Results of Modern Methods of Treatment in Sanatoriums.

Dr. Cameron St. Clair Guild, New York, The Problem and a Program for Combating Tuberculosis Among Negroes.

Dr. Paul A. Teschner, assistant director, Bureau of Health Education, American Medical Association, Chicago, Interpreting Tuberculosis to Ready-Made Audiences.

Dr. Jay Arthur Myers, Minneapolis, Modern Concepts of Tuberculosis (in a symposium).

Dr. Everts A. Graham, St. Louis, Extrapleural Pneumothorax.

Death Rates in Large Cities in 1937.—The New York City Department of Health has issued its annual tabulation of death rates in twenty-seven large cities of the United States, prepared from information furnished by the health officers of the cities. Detroit had the lowest rate of any of the cities listed, 8.6 per thousand of population, and Denver the highest, 15.9. For the five largest cities the rates were: New York 10.4, Chicago 10.3, Philadelphia 12.4, Detroit 8.6, and Los Angeles 12.8. The average rate for the twenty-seven cities, which have an estimated population of 27,000,000, was 11.6. Rochester, N. Y., showed the lowest infant mortality rate, 32 per thousand births. San Francisco was second with 32.6 and Jersey City, N. J., had a rate of 32.9. New Orleans had the highest rate, 78.3. The average birth rate was 15.3. The highest birth rate occurred in Jersey City, 20.7, and Denver was second with 20.1. The lowest was in San Francisco, 11.9.

Pharmacists Urge Freedom of Choice in Medical Care.—The American Pharmaceutical Association at its recent annual meeting in Minneapolis adopted a resolution pledging its cooperation in devising suitable plans for the utilization of the present existing agencies that provide medical services. The resolution emphasized especially that the association urges the retention of free choice of physician, dentist, pharmacist and nurse by the patient as an essential feature in whatever system may be adopted. At the Minneapolis meeting the association's committee on study of pharmacy was renamed the "committee on social and economic relations" in view of the fact that its duties have been enlarged to include consideration of employer-employee relations, governmental participation in supplying necessary health services and other matters involving the relation of pharmacy to the social and economic structure.

Center for Training in Safety Education.—The National Conservation Bureau of the Association of Casualty and Surety Executives in cooperation with New York University has set up at the university a national center for the training of

teachers and supervisors in the field of safety. Ned H. Dearborn, dean of the division of general education at the university, is chairman of an advisory committee and Albert W. Whitney, consulting director of the National Conservation Bureau, is vice chairman. Herbert J. Stack is director of the new center. Activities of the center will be in four main divisions: graduate courses in safety education for city and state supervisors, research on preparation of books and manuals for carrying on safety activities, field and consultant work, and the publication and distribution of courses of study, books, visual aids and other educational publications. Twenty-eight fellowships and scholarships are to be awarded this year for courses, many of them leading to an advanced degree. Several of the courses will be given in other centers near New York.

Symposium on Mental Health.—The American Association for the Advancement of Science announces that a symposium on mental health will be presented at the midwinter meeting in Richmond, Va., December 28-30, under the chairmanship of Dr. Walter L. Treadway, assistant surgeon general, U. S. Public Health Service. Six sectional sessions will be held over the three days and a general discussion session will conclude the symposium Friday evening December 30. Chairmen for the sessions have been named as follows: Drs. Clarence M. Hincks, New York, mental health administration; Nolan D. C. Lewis, New York, research into mental illness; Franklin G. Ebaugh, Denver, professional education; Abraham Myerson, Boston, community sources of mental disorders—their amelioration and prevention; Harry Stack Sullivan, New York, physical and cultural environment in relation to the conservation of mental health, and Joseph Zubin, Ph.D., U. S. Public Health Service, economic aspects of mental disease. Papers will not be read at these sessions but will be published before the meeting and used as a basis for discussion. The program committee is made up of the session chairmen and the following additional members: Drs. Samuel W. Hamilton and Grover A. Kempf, New York; Roscoe W. Hall, Washington, D. C.; James S. Plant, Newark, N. J.; Malcolm H. Soule, LL.D., Ann Arbor, Mich., and Paul O. Komora, associate secretary, National Committee for Mental Hygiene. Communications should be addressed to Symposium on Mental Hygiene, American Association for the Advancement of Science, Room 822, 50 West Fiftieth Street, New York.

American Hospital Association.—The fortieth annual convention of the American Hospital Association will be held in Dallas, Texas, September 26-30, under the presidency of Robert E. Neff, Iowa City. Among speakers who will address general and section meetings will be:

Dr. John H. Musser, New Orleans, Significant Nutritional Developments to Be Considered in Institutional Food Service.

Edward H. Lewinski-Corwin, Ph.D., New York, The Hospital of the Future.

Arthur J. Altmeyer, chairman, Social Security Board, Washington, D. C., The Relation of Hospital Service to a National Health Program.

Dr. Harry E. Kleinschmidt, New York, The Role of the General Hospital in the Control of Tuberculosis.

Dr. Hugh Leslie Moore, Dallas, Control of Infection in a Children's Hospital.

Other features will be a panel discussion on hospital care insurance, clinical demonstrations on emergency room technic and orthopedic work, and various round table discussions. Meeting in conjunction with the association will be the American Protestant Hospital Association September 23-25, the National Association of Nurse Anesthetists September 26-30 and the American College of Hospital Administrators September 25-26.

CANADA

New Dean Appointed at Montreal.—Dr. Joseph Albert LeSage, professor of clinical medicine, University of Montreal Faculty of Medicine, Montreal, Que., has been appointed dean of the medical faculty to succeed Dr. T  lesphore Parizeau, who has retired. Dr. Georges H. Baril, professor of physiologic chemistry, has been made director of studies.

LATIN AMERICA

Meeting of Orthopedic Surgeons.—The third congress of the Brazilian Society of Orthopedics and Traumatology was held in Recife, Pernambuco, Brazil, July 1-3, under the presidency of Dr. Luiz Barros, Lima, professor of orthopedic surgery, Faculty of Medicine of Recife. The principal subjects for discussion were "Fractures of the Ankle" and "Sequelae

of Infantile Paralysis." The next congress will be held in São Paulo in July 1940 and the subjects to be discussed are "Fractures of the Spine" and "Lumbar Pains."

FOREIGN

Society News.—The International Spa Federation will hold a meeting in Berlin September 22-23 and the International Spa Congress will be held at Bad Nauheim September 24-27 in conjunction with the second German Balneological Conference. Arrangements are being made by the Reichsfremdenverkehrsverband, Berlin W. 9, Potsdamer Platz 1. —The Italian Society of Obstetrics and Gynecology will hold its thirty-fifth congress at Perugia October 16-18, instead of Pisa September 20, as previously planned. Subjects announced for discussion are chorionepithelioma, female sterility, painless labor and insurance on maternity.

Government Services

Training Course for Fifth Corps Area Reserves

A medicodental military inactive status training course will be held at Cleveland October 3-15 with the cooperation of eight Cleveland hospitals, Western Reserve University and the Cleveland Academy of Medicine. A professional program will be presented for medical and dental officers separately in the mornings and a military program for all officers attending in the afternoons and certain evenings. One hundred hours of inactive status training credits will be granted to all reserve officers completing the course. Inquiries should be addressed to: Headquarters, Organized Reserves, 538 Federal Building, Cleveland.

Changes in the Food and Drug Administration

Dr. James J. Durrett, chief of the drug division of the Food and Drug Administration, U. S. Department of Agriculture, has been made principal technical adviser attached to the office of the chief of the administration, according to an announcement of changes in personnel made necessary by the enactment of the new federal food, drug and cosmetic law. Dr. Durrett will share with other officers the responsibility of determining administrative questions in the application of the new law and will give special consideration to the adequacy of information submitted by manufacturers with their applications on new drugs filed in compliance with the provisions of the act. Dr. Theodore G. Klumpp, now senior medical officer of the drug division, succeeds Dr. Durrett as chief of that division. Dr. Klumpp graduated from Harvard University Medical School, Boston, in 1928.

Physicians Needed for CCC Duty

The surgeon of the Eighth Corps Area, U. S. Army, announces that physicians are needed for duty in the Civilian Conservation Corps. Applicants must be graduates of class A medical schools and preference will be given to medical reserve officers of the grades of first lieutenant or captain. The monthly pay status is as follows:

1. Captains, medical corps reserve, with dependents, having over seven and less than seventeen years' service, \$336.
2. Captains, medical corps reserve, without dependents, having over seven and less than seventeen years' service, \$298.
3. Married first lieutenants, medical corps reserve, \$262.67, including allowances.
4. Unmarried first lieutenants, medical corps reserve, \$224.67.
5. Civilian physicians placed on duty as contract physicians, \$200 if single; \$265 if married.

Assignment preference of applicants will be granted when practicable within the five states comprising the eighth corps area: Arizona, Colorado, New Mexico, Oklahoma, Texas and Wyoming. Inquiries should be addressed to the Surgeon, Headquarters, Eighth Corps Area, Fort Sam Houston, Texas.

CORRECTION

Anatomic Factors in Pathogenesis and Treatment of Urethrocele and Cystocele.—In a paper by this title by Curtis, Anson and McVay, in *THE JOURNAL*, September 3, the words "which ensheath" should have been inserted in the fourth line of the summary following the words "the endopelvic fascia" on p. 905.
